

# COMPSCI 105 S1 2017

## Principles of Computer Science

16 Queue(2)

# Agenda & Readings

---

## ▶ Agenda

- ▶ Using the Queue ADT to solve problems
- ▶ A Circular Queue
- ▶ The Deque Abstract Data Type

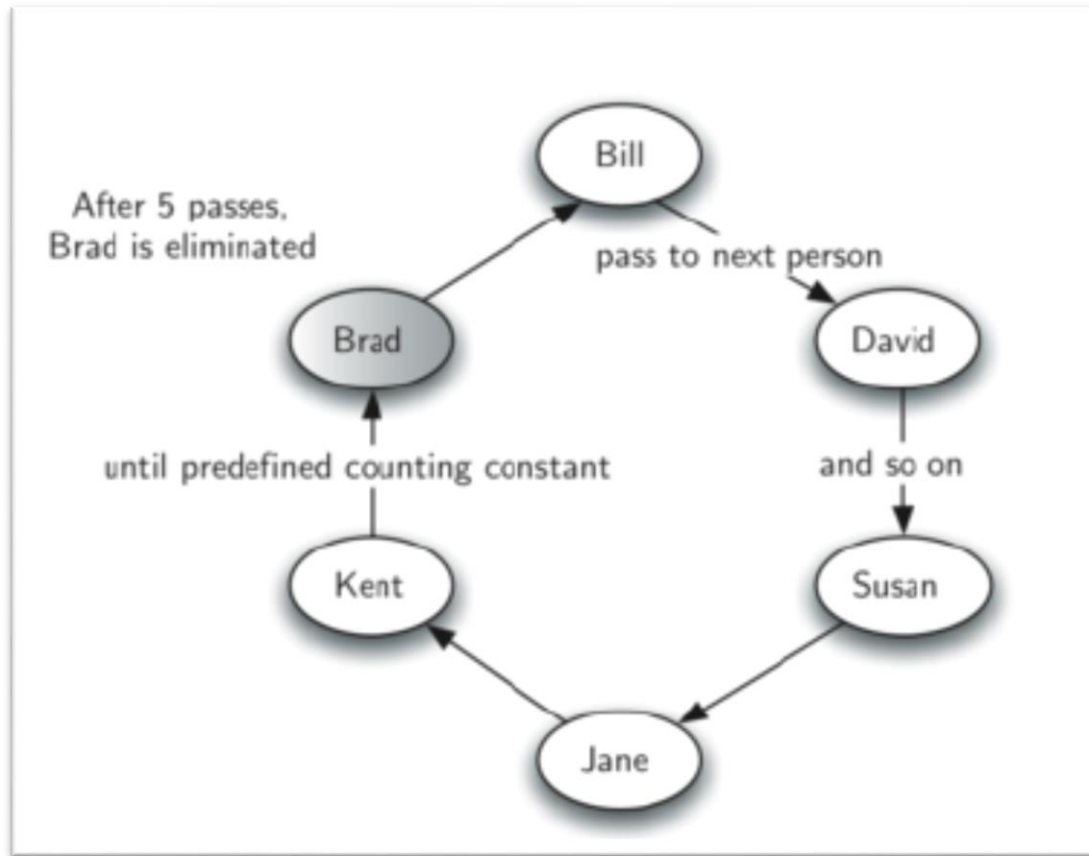

## ▶ Reference:

- ▶ Textbook: Problem Solving with Algorithms and Data Structures
  - Chapter 3: Basic Data Structures

# Simulation: Hot Potato

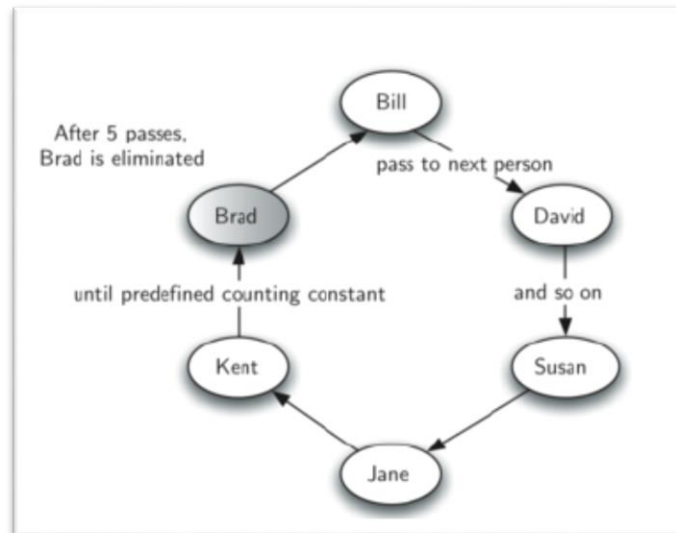

- ▶ Example (six persons game):

# Simulation: Hot Potato

- ▶ **Example (six persons game):**
  - ▶ Children form a circle and pass an item from neighbour to neighbour as fast as they can
  - ▶ At a certain point in the game, the action is stopped and the child who has the item (the potato) is removed from the circle
  - ▶ Play continues until only one child is left

# Simulation: Hot Potato

▶ Example (hotPotato([Bill, David, Susan, Jane], 3)):

Round 1

dequeue

|       |       |       |       |
|-------|-------|-------|-------|
| Bill  | David | Susan | Jane  |
| David | Susan | Jane  | Bill  |
| Susan | Jane  | Bill  | David |
| Jane  | Bill  | David | Susan |

enqueue

Round 2

|       |       |       |
|-------|-------|-------|
| Bill  | David | Susan |
| David | Susan | Bill  |
| Susan | Bill  | David |
| Bill  | David | Susan |

## 16.1 Applications

# Simulation: Hot Potato

- ▶ Example (`hotPotato([Bill, David, Susan, Jane], 3)`):

Round 3

|       |       |
|-------|-------|
| David | Susan |
| Susan | David |
| David | Susan |
| Susan | David |

Final

David

WIN!

## 16.1 Applications

# Simulation: Hot Potato

### ► Code:

```
def hotPotato(namelist, num):  
    simqueue = Queue()  
    for name in namelist:  
        simqueue.enqueue(name)  
    while simqueue.size() > 1:  
        for i in range(num):  
            simqueue.enqueue(simqueue.dequeue())  
        simqueue.dequeue()  
    return simqueue.dequeue()
```

Move element from  
the front of the queue  
to the end

Return the name  
when there is only  
ONE name remains in  
the queue

## 16.2 Circular Queue

# Circular Queue

- ▶ What is the Big-O performance of enqueue and dequeue of the implementation using Python List?

- ▶ enqueue(...):  $O(n)$

We have to shift all list elements by one position to make room for the new item

- ▶ Shifting array elements to the right after each addition – too Expensive!

- ▶ dequeue() :  $O(1)$

- ▶ Another Implementation: **Circular Queue**

- ▶ enqueue & dequeue :  $O(1)$

- ▶ Items can be added/removed without shifting the other items in the process

Viewed as a circle instead of line

Avoid the “shifting” of list elements by one position to make room for the new item

# Circular Queue - Set up

---

- ▶ Uses a Python list data structure to store the items in the queue
- ▶ There are three critical variables:
  - ▶ **front**: indicates the location of the item at the front
  - ▶ **back**: indicates the location of the item at the back
  - ▶ **count**: indicates the number of items in the queue
- ▶ The list has an initial capacity (all elements None)

# Circular Queue - Set up

- ▶ Keeps an index of the current **front** of the queue and of the current **back** of the queue
  - ▶ set **front** to 0
  - ▶ set **back** to  $\text{MAX\_QUEUE} - 1$
  - ▶ set **count** to 0
- ▶ New items are **enqueued** at the **back** index position
- ▶ Items are **dequeued** at the **front** index position.
- ▶ A **counting** of the queue items to detect queue-full and queue-empty conditions

To initialize the queue

# Circular Queue - How To Advance

- ▶ Queue-empty:
  - ▶ **front** is one slot ahead of **back**
- ▶ When either front or back advances past  $\text{MAX\_QUEUE} - 1$ , it wraps around to 0
- ▶ The wrap-around effect: by using Modulus (%) arithmetic operator

```
def enqueue(self, item): # if not full
    self.back = (self.back + 1) % self.MAX_QUEUE
    self.items[self.back] = item
    self.count += 1
def dequeue(self): # if not empty
    item = self.items[self.front]
    self.front = (self.front + 1) % self.MAX_QUEUE
    self.count -= 1
    return item
```

## 16.2 Circular Queue Enqueue

### ▶ Example:

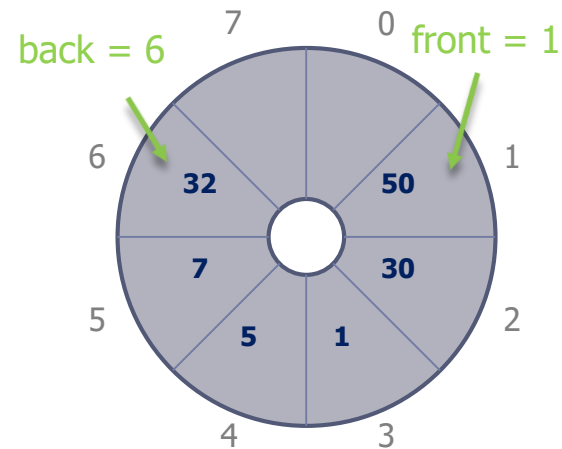

▶ `q.enqueue(32)`

- ▶ **back** is advanced by one position
- ▶ New item is inserted at the position of **back**
- ▶ **count** is incremented by 1

```
def enqueue(self, item): # if not full
    self.back = (self.back + 1) % self.MAX_QUEUE
    self.items[self.back] = item
    self.count += 1
```

size = 8; count = 5

size = 8; count = 6

## 16.2 Circular Queue Dequeue

### ▶ Example:

#### ▶ q.dequeue()

- ▶ Value in front position is returned
- ▶ **front** is advanced by 1
- ▶ **count** is decremented by 1

```
def dequeue(self): # if not empty
    item = self.items[self.front]
    self.front = (self.front + 1) % self.MAX_QUEUE
    self.count -= 1
    return item
```

size = 8; count = 6

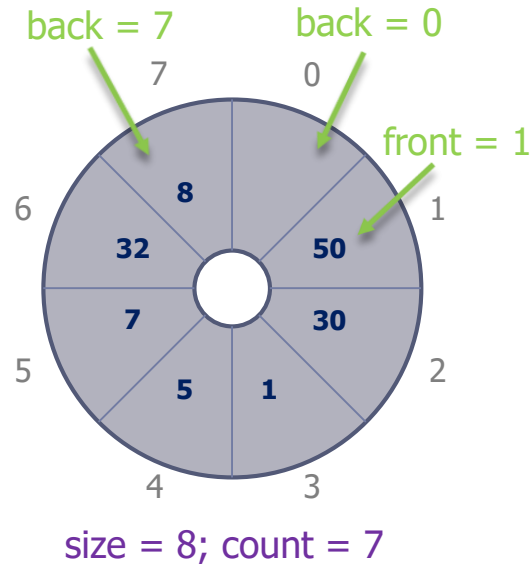

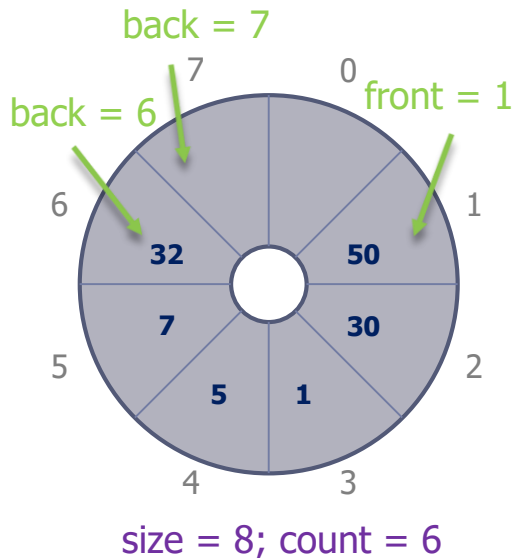

size = 8; count = 5

# 16.2 Circular Queue

## Enqueue

- ▶ `q.enqueue(8)`
  - ▶ After running the first enqueue, `back = 7`
- ▶ `q.enqueue(20)`
  - ▶ After running the second enqueue, `back = 0` as the “`back`” is wrapped around the list

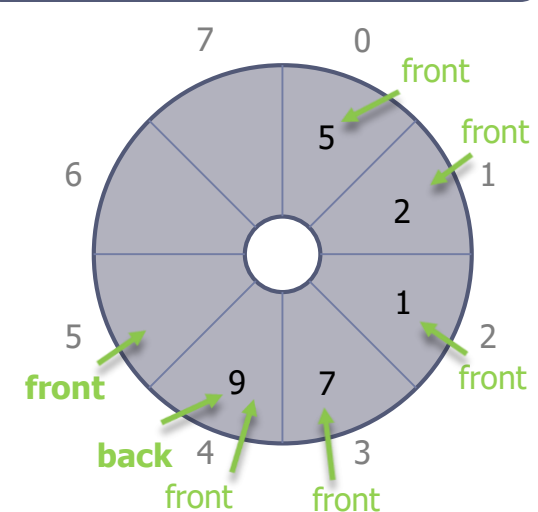

## 16.2 Circular Queue

# Full & Empty

- ▶ **front** and **back** cannot be used to distinguish between queue-full and queue-empty conditions for a circular array

```
q = QueuedCircular(8)  
  
q.enqueue(5)  
q.enqueue(2)  
q.enqueue(1)  
q.enqueue(7)  
q.enqueue(9)  
  
q.dequeue()  
q.dequeue()  
q.dequeue()  
q.dequeue()  
q.dequeue()
```

$$\text{back} = \text{front} - 1$$

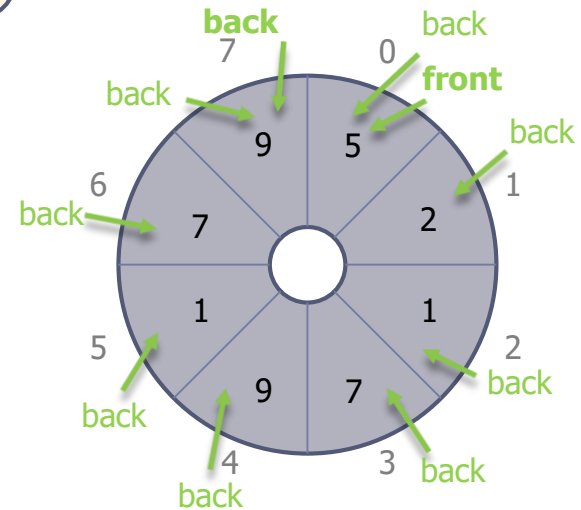

## 16.2 Circular Queue

# Full & Empty

- ▶ **front** and **back** cannot be used to distinguish between queue-full and queue-empty conditions for a circular array

```
q = Queuercircular(8)
q.enqueue(5)
q.enqueue(2)
q.enqueue(1)
q.enqueue(7)
q.enqueue(9)
q.enqueue(1)
q.enqueue(7)
q.enqueue(9)
```

```
def is_empty():
    return self.count == 0
```

```
def is_full():
    return self.MAX_QUEUE <= self.count
```

## 16.2 Circular Queue

# Exercise 1

- ▶ What are the values of “front” and “back” after executing the following code fragment?

```
q = Queuecircular(10)
q.enqueue(12)
q.enqueue(17)
q.enqueue(25)
q.enqueue(11)
q.dequeue()
q.dequeue()
q.enqueue(30)
```

## 16.3 Deque

# Deque Abstract Data Type

---

- ▶ **Deque - Double Ended Queue**
  - ▶ A deque is an ordered collection of items where items are added and removed from either end, either front or back
  - ▶ The newest item is at one of the ends

# Deque Abstract Data Type

---

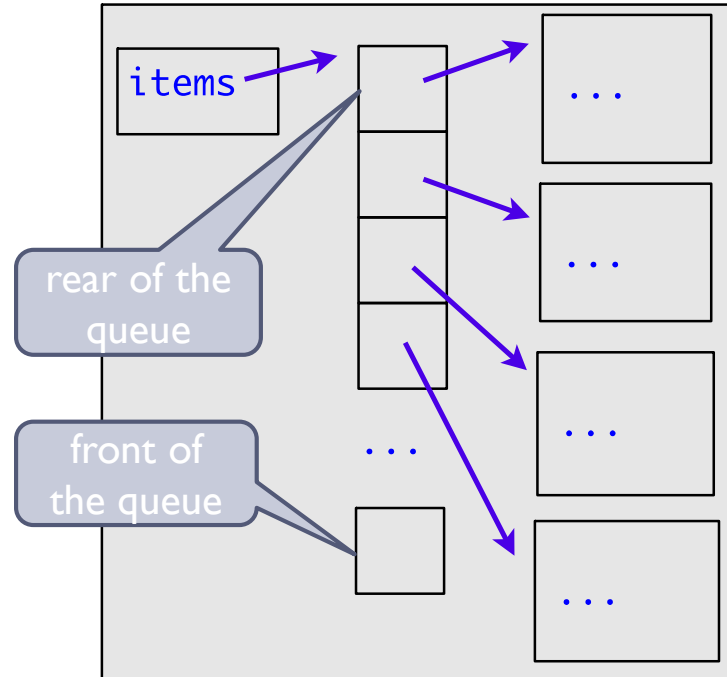

- ▶ What are the operations which can be used with a Deque Abstract Data?
- ▶ Create an empty deque:
- ▶ Determine whether a deque is empty:
- ▶ Add a new item to the deque:
  - ▶ `add_front()`
  - ▶ `add_rear()`
- ▶ Remove from the deque the item that was added earliest:
  - ▶ `remove_front()`
  - ▶ `remove_rear()`

# Code Example

- ▶ We use a python **List** data structure to implement the deque

```
class Deque:  
    def __init__(self):  
        self.items = []  
  
    ...  
    def add_front(self, item):  
        self.items.append(item)  
    def add_rear(self, item):  
        self.items.insert(0,item)  
    def remove_front(self):  
        return self.items.pop()  
    def remove_rear(self):  
        return self.items.pop(0)
```

**Big-O?**  
add\_front()/remove\_front():  $O(1)$   
add\_rear()/remove\_rear():  $O(n)$

## 16.3 Deque

# Code Example

### ► Code:

```
d.is_empty()
d.add_rear(4)
d.add_rear('dog')
d.add_front('cat')
d.add_front(True)
d.size()
d.is_empty()
d.add_rear(8.4)
d.remove_rear()
d.remove_front()
```

```
d = []
d = [4]
d = ['dog', 4]
d = ['dog', 4, 'cat']
d = ['dog', 4, 'cat', True]
d = ['dog', 4, 'cat', True]
d = ['dog', 4, 'cat', True]
d = [8.4, 'dog', 4, 'cat', True]
d = ['dog', 4, 'cat', True]
d = ['dog', 4, 'cat']
```

True

4

False

8.4

True

## 16.3 Deque

# Application: Palindrome Checker

- ▶ A string which reads the same either left to right, or right to left is known as a palindrome
  - ▶ Radar
  - ▶ deed
  - ▶ A dog, a plan, a canal: pagoda

# Palindrome Checker - Algorithm

- ▶ Create a **deque** to store the characters of the string
  - ▶ The **front** of the **deque** will hold the **first** character of the string and the **rear** of the **deque** will hold the **last** character
- ▶ Remove both of them directly, we can compare them and continue only if they match
  - ▶ If we can keep matching first and the last items, we will eventually either **run out of characters** or be left with a **deque of size 1**
    - ▶ In either case, the string must be a palindrome

## 16.3 Deque

# Palindrome Checker - Examples

---

- ▶ `print(pal_checker("lsdkjfskf"))`
  - ▶ Queue: f, k, s, f, j, k, d, s, l
  - ▶ 1<sup>st</sup> round: compare **f** and **l** => **FALSE**, STOP
- ▶ `print(pal_checker("radar"))`
  - ▶ Queue: r, a, d, a, r
  - ▶ 1<sup>st</sup> round: compare **r** (front) and **r** (back)
  - ▶ 2<sup>nd</sup> round: compare **a** (front) and **a** (back)
  - ▶ 3<sup>rd</sup> round: `size() = 1`, STOP, return **TRUE**

## 16.3 Deque

# Palindrome Checker - Codes

### ▶ Check:

- ▶ The front of the deque (the first character of the string)
- ▶ The rear of the deque (the last character of the string)

```
still_equal = True
while char_deque.size() > 1 and still_equal:
    first = char_deque.remove_front()
    last = char_deque.remove_rear()
    if first != last:
        still_equal = False
return still_equal
```

# Summary

---

- ▶ To distinguish between the queue-full and queue-empty conditions in a queue implementation that uses a circular array
  - ▶ By counting the number of items in the queue
- ▶ Models of real-world systems often use queues
