

A large teal rounded rectangle is centered on the slide. It contains the text 'CS 773 Features', 'Chia-Yen Chen', and 'Dept. of Computer Science The University of Auckland yen@cs.auckland.ac.nz'. The rectangle is surrounded by various colored circles (orange, yellow, grey, teal, white) of different sizes. A small teal square is in the top-left corner. A small teal circle with the number '1' is in the bottom-right corner.

# CS 773

## Features

Chia-Yen Chen

Dept. of Computer Science  
The University of Auckland  
*yen@cs.auckland.ac.nz*

# Features in images

*Something interesting in the image*

- Spatial structures in the image
  - Point
  - Edge
  - Corner
  - Shape

- Characteristics revealed as the result of some operations
  - Feature detection

# Examples of matched feature points

● Left/right images

● Successive frames

# Corners

- The point at which the direction of the boundary of object changes abruptly
- Intersection point between two or more edge segments

The two figures show an artificial and a real image, respectively, with the corners indicated in red.

# Feature Point detection

The corner detectors should satisfy the following criteria:

- All (or most) the true feature points should be detected.
- No false feature points should be detected.
- Feature points should be well localized.
- Feature point detector should be robust with respect to noise.
- Feature point detector should be efficient.

# Feature Point detection

Two families of corner detectors

1. Algorithms that work directly with the values of brightness of images (without segmenting the image in advance)
  - Usually based on the study of derivatives (orientation, magnitude) of grey level or colour image
2. Algorithms that extract object boundaries first and analyze its shape afterwards
  - Boundaries often assumed to be extracted by edge-detectors
  - Usually based on the analysis of the curvature of boundaries

Group 2 seems to offer less reliability (use edge detectors for boundary extraction is not working well) and slower solutions.

# The Harris-Plessey detector

Basic idea: Look at changes of Intensity in any direction on a small windows over any given point.

- Flat region: no change in all directions
- Edge: no change along the edge direction
- Corner: significant change in most directions

# The Harris-Plessey detector

Change of intensity

- $\sum_w [I(x + u, y + v) - I(x, y)]^2$

By Taylor series expansion, first order approximation for 2D function

- $I(x + u, y + v) \approx I(x, y) + uI_x(x, y) + vI_y(x, y)$

$$\begin{aligned} & \sum_w [I(x + u, y + v) - I(x, y)]^2 \\ & \approx \sum_w [I(x, y) + uI_x(x, y) + vI_y(x, y) - I(x, y)]^2 \\ & = \sum_w [u^2 I_x(x, y)^2 + 2uv I_x(x, y) I_y(x, y) + v^2 I_y(x, y)^2] \end{aligned}$$

# The Harris-Plessey detector

- The following 2x2 symmetric matrix is considered at each image point (pixel) of the image

$$M = \begin{bmatrix} \sum_w \left( \frac{\partial I}{\partial x}(x, y) \right)^2 & \sum_w \left( \frac{\partial I}{\partial x}(x, y) \frac{\partial I}{\partial y}(x, y) \right) \\ \sum_w \left( \frac{\partial I}{\partial y}(x, y) \frac{\partial I}{\partial x}(x, y) \right) & \sum_w \left( \frac{\partial I}{\partial y}(x, y) \right)^2 \end{bmatrix}$$

$I(x, y)$ : image intensity at point  $(x, y)$

# The Harris-Plessey detector

- By evaluating the eigenvalues of the matrix  $M$ , we can detect the image feature by following rules:
  1. If both eigenvalues are small, the intensity of the windowed image region is approximately constant (homogeneous region).
  2. If one eigenvalue is high and the other is low, this indicates an edge.
  3. If both eigenvalues are sufficiently large, the point is declared to be a corner.

# The Harris-Plessey detector

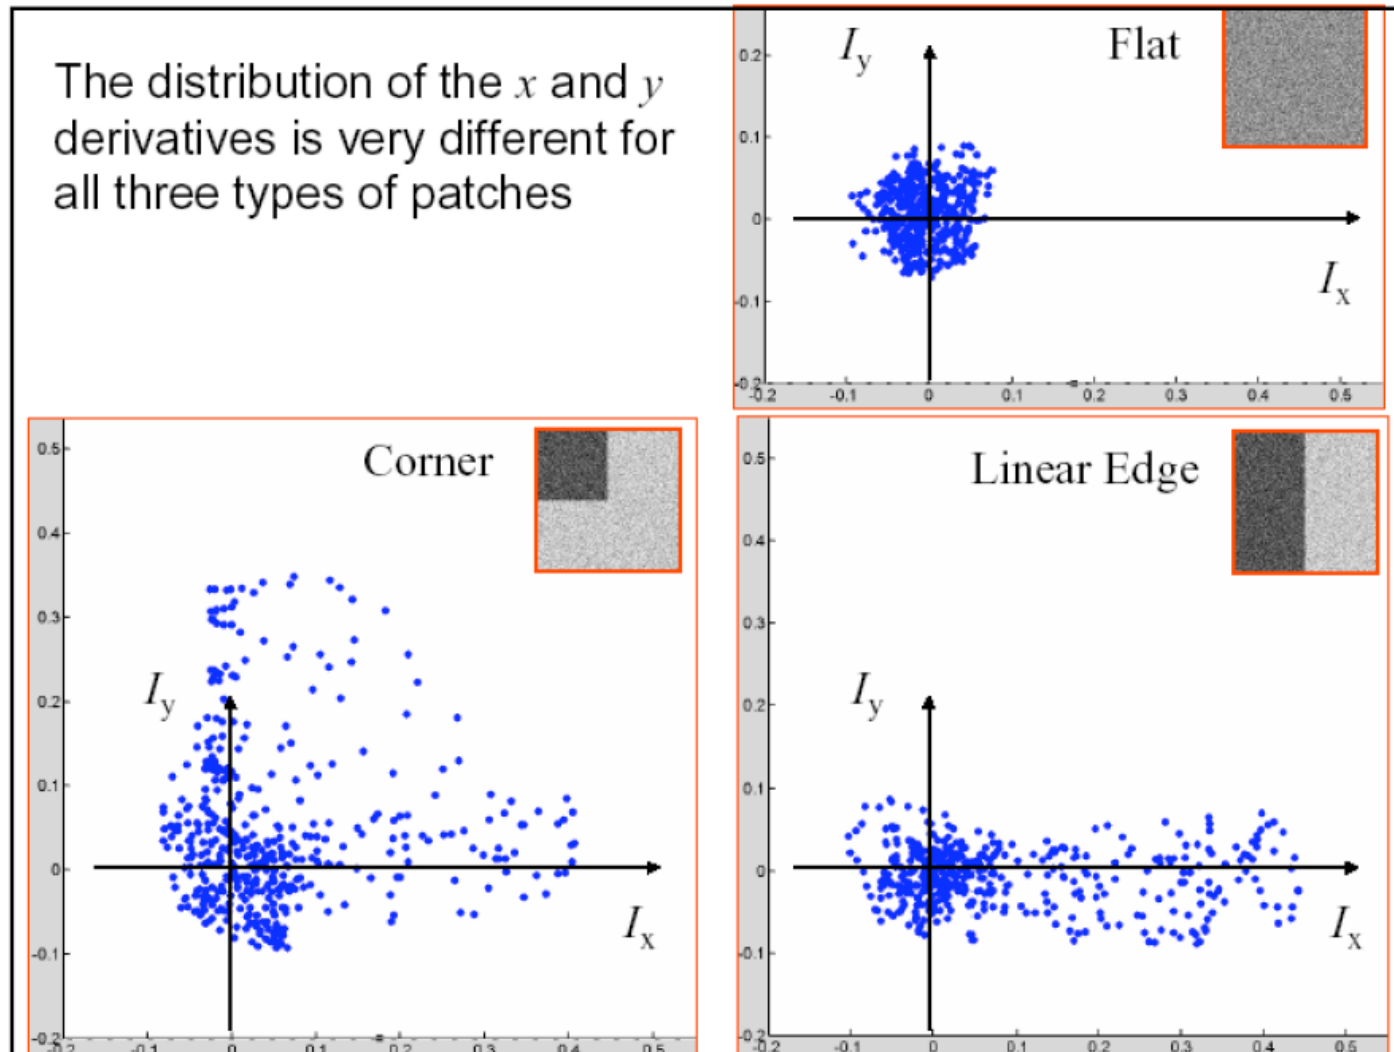

- Treat gradient vectors as a set of  $(dx,dy)$  points with a center of mass defined as being at  $(0,0)$ .
- Fit an ellipse to that set of points via scatter matrix
- Analyze ellipse parameters for varying cases

# Examples

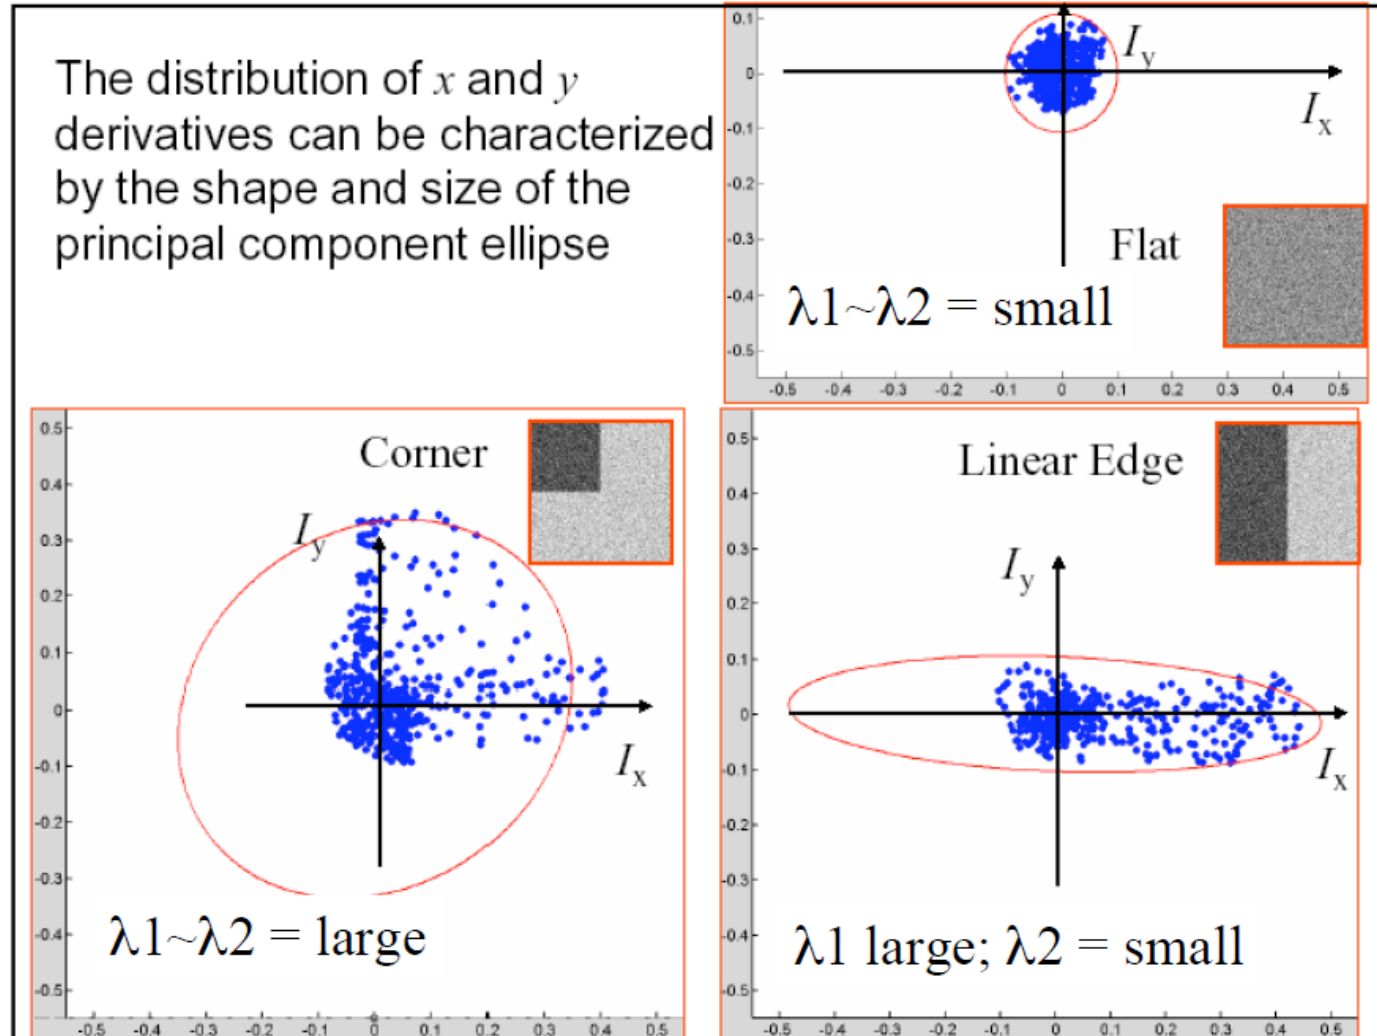

# Examples

- Plotting derivatives as 2D points

# Examples

- Ellipse fitting

# The Harris-Plessey detector

Classification of image points using eigenvalues of  $M$ :

Modified from: [http://www.wisdom.weizmann.ac.il/~deniss/vision\\_spring04/files/InvariantFeatures.ppt](http://www.wisdom.weizmann.ac.il/~deniss/vision_spring04/files/InvariantFeatures.ppt)

# The Harris-Plessey detector

- In the Harris implementation, the corner is calculated as the ratio:

$$R_p = \frac{\text{Trace}(M)}{\text{Det}(M)}$$

- Thus, a point is marked as a corner if the value of  $R_p$  is less than the threshold and is the local minimum.
- Deemed unstable

A good (corner) point should have a *large intensity change in all directions*, i.e.  $R$  should be large positive

# The Harris-Plessey detector

Measure of corner response:

- $R = \text{Det}(M) - k(\text{Trace}(M))^2$
- $\text{Det}(M) = \lambda_1 \lambda_2$
- $\text{Trace}(M) = \lambda_1 + \lambda_2$
- $k$  – empirical constant,  $k = 0.04-0.15$

- $R$  depends only on eigenvalues of  $M$
- $R$  is large for a corner
- $R$  is negative with large magnitude for an edge
- $|R|$  is small for a flat region

$$R = \lambda_1 \lambda_2 - 0.04(\lambda_1 + \lambda_2)^2$$

# The Algorithm

1. Compute  $x$  and  $y$  derivatives of image

$$I_x = G_\sigma^x * I \quad I_y = G_\sigma^y * I$$

2. Compute products of derivatives at every pixel

$$I_{x2} = I_x \cdot I_x \quad I_{y2} = I_y \cdot I_y \quad I_{xy} = I_x \cdot I_y$$

3. Compute the sums of the products of derivatives at each pixel

$$S_{x2} = G_{\sigma^2} * I_{x2} \quad S_{y2} = G_{\sigma^2} * I_{y2} \quad S_{xy} = G_{\sigma^2} * I_{xy}$$

4. Define at each pixel  $(x, y)$  the matrix

$$H(x, y) = \begin{bmatrix} S_{x2}(x, y) & S_{xy}(x, y) \\ S_{xy}(x, y) & S_{y2}(x, y) \end{bmatrix}$$

5. Compute the response of the detector at each pixel

$$R = \text{Det}(H) - k(\text{Trace}(H))^2$$

6. Threshold on value of  $R$ . Compute nonmax suppression.

# Examples

Coded  $R$ : negative  $R$  in red; positive  $R$  in blue

# Examples

Find points with large corner response:  
 $R > \text{threshold}$

Take only the points of local  
maxima of  $R$

# Examples

Threshold:  $R < -10000$   
(edges)

# Examples

Threshold:  $> 10000$   
(corners)

# Examples

Threshold:  $-10000 < R < 10000$   
(neither edges nor corners)
