Abstract—We present in this document experimental results that have not been included in [1] because of the limited space.

The results shown in Sec. I are for the evaluation of DLU when the missing data are simulated by sampling without replacement (see also [1, Sec. IV]). Each table in Sec. I contains the normalized errors computed for a time series from the dataset of $K = 20$ time series, when various imputation methods are applied.

In the caption of the table, we mention the acronym of the time series as well as the transformations that have been applied for the methods Trend, Trend+DL, Trend+imputeTS and Trend+MTSDI. For example, for the first time series in the dataset (TS₁), we write the following in the caption of the Table I: $p = 3$, $\omega_1 = 1/24$, $\omega_2 = 1/12$, $\omega_3 = 1/8$. This means that three periodic components have been removed, and their frequencies are $\omega_1, \omega_2, \omega_3$. Similarly, for TS₅, we write $\theta_1 = 16$ in the caption of Table V for indicating that the time series z was transformed by computing the differences $z_t - z_{t-\theta_1}$ for all the time points t . We emphasize that the linear trend is removed from *all* time series and this transformation is not mentioned in the captions of the tables.

The symbol ρ stands for the percentage of the missing data. For each value of ρ , the smallest normalized error is written in red and the second smallest is written in bold. For ease of comparison, we plot in Fig. 1 the scores of the imputation methods, which are computed according to the rules given [1, Sec. IV]. In Fig. 2, we show the best and the second best result for each time series. Each panel of the figure corresponds to a particular value of ρ .

The results in Sec. II are also for the evaluation of the DLU imputation method, but this time the missing data are produced by using the Polya urn model (see again [1, Sec. IV]). All the conventions for the tables within this section are the same as the conventions for the tables in Sec. I. The graphical settings in Fig. 3 are the same as in Fig. 1; Fig. 4 is similar to Fig. 2.

The results for DLM are presented in Sec. III, where some information about the experimental settings is provided (see also [1, Sec. V]).

TABLE XL: TS_{20} : $p = 4$, $\omega_1 = 1/168$, $\omega_2 = 1/28$, $\omega_3 = 1/24$, $\omega_4 = 1/12$.

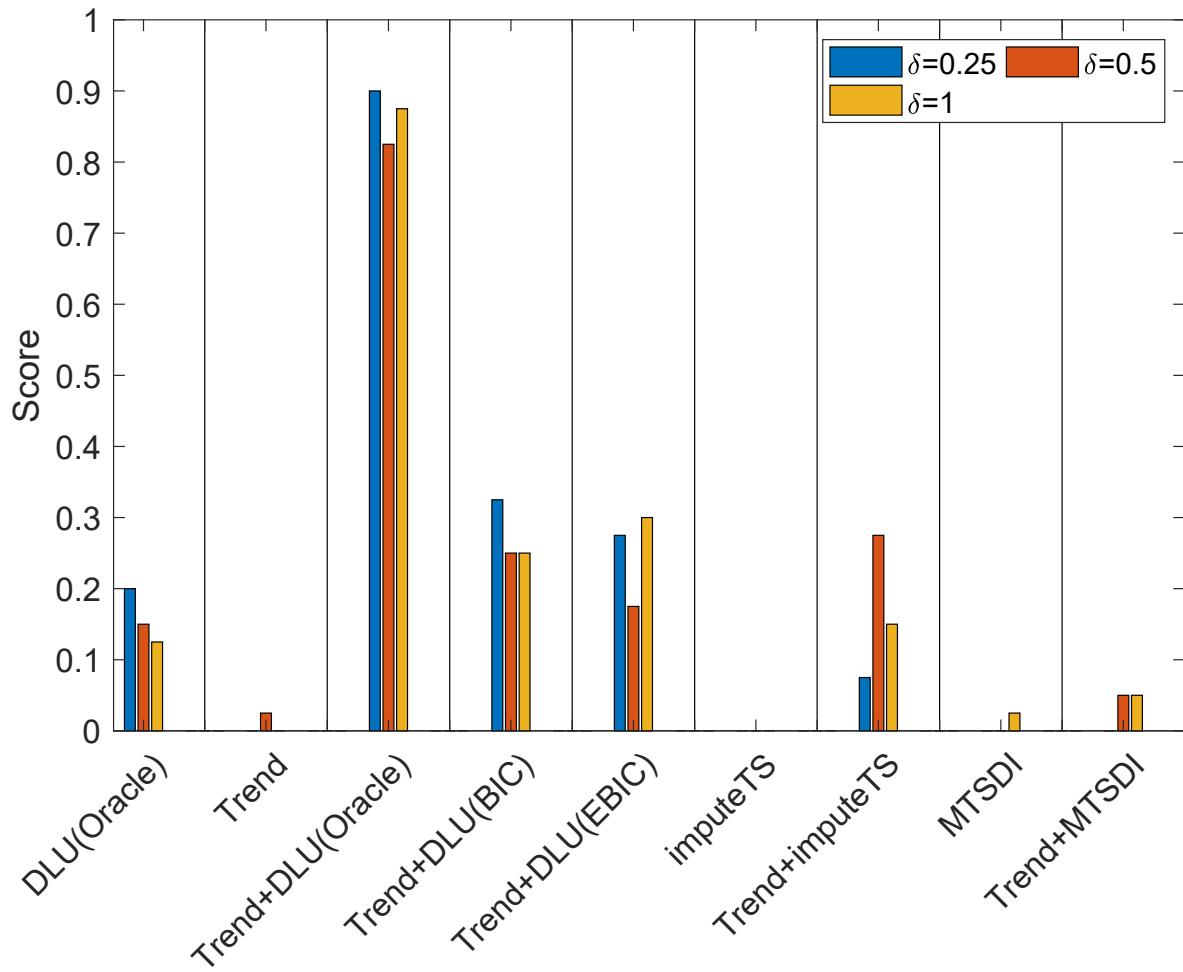

Fig. 3: Missing data generated by using the Polya urn model: Scores for the imputation methods are based on the results reported in Tables XXI-XL. The parameter M for the Polya urn model takes value 5; the values of the parameter δ are given in the legend. The percentage of the missing data is $\rho = 5\%$.

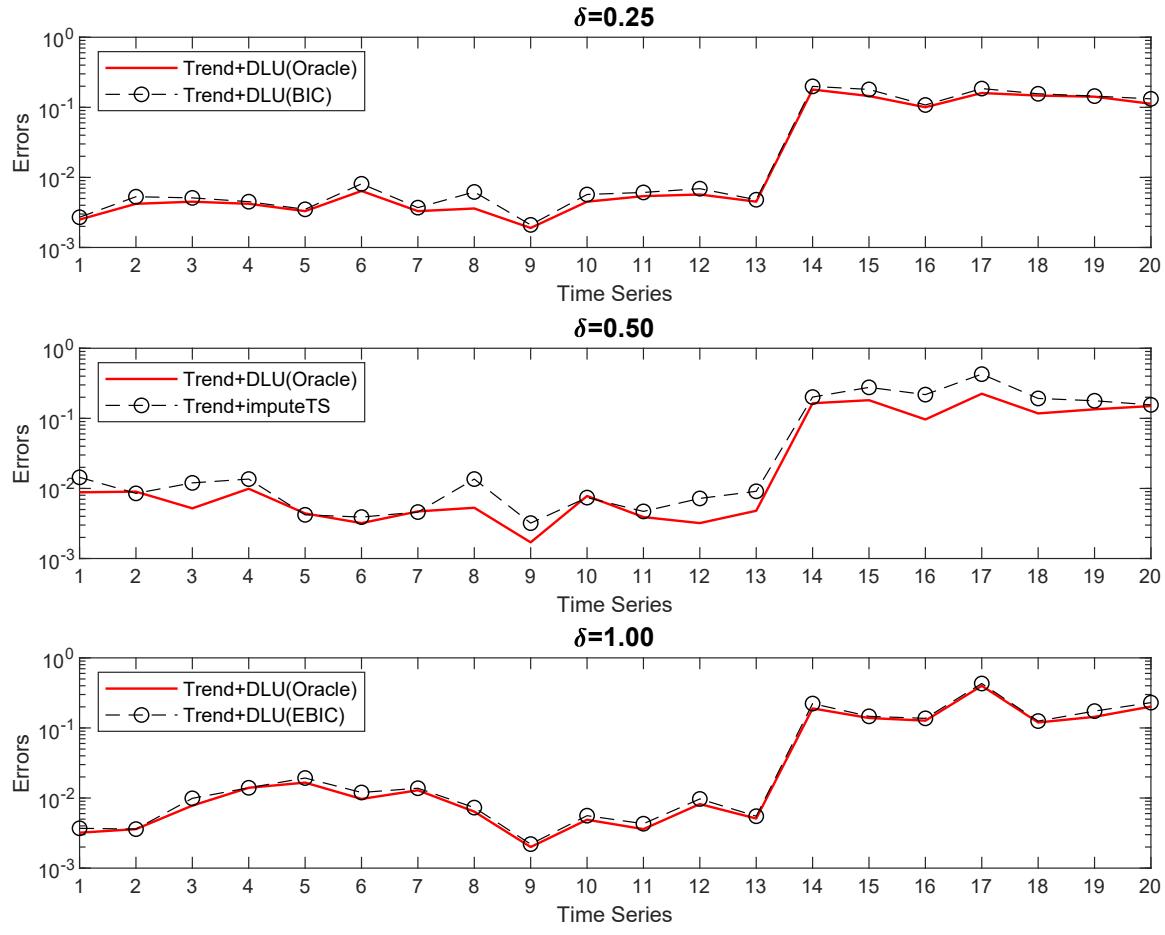

Fig. 4: Missing data generated by using the Polya urn model: For each time series, the normalized errors are represented with the same graphical conventions as in Fig. 2.

III. DLM: EXPERIMENTAL RESULTS

Some explanations about the normalized errors shown in Table XLI:

- The percentage of the missing data for each time series is $\rho = 5\%$, and the missing data are simulated by sampling without replacement.
- When applying imputation methods that contain the word “Trend” in the acronym, the linear trend is removed from all three time series. From the time series VIC and SA are also removed two periodic components with frequencies $\omega_1 = 1/12$ and $\omega_2 = 1/3$.
- The symbol n denotes the size of the dictionary and s stands for the sparsity of the dictionary. In the case of DLM, $n_4 = n_{K+1}$ because the number of time series is $K = 3$; n_4 denotes the size of the dictionary block that is common for all time series. The symbol n_u represents the number of atoms used in the representation of each time series.
- The imputation methods that involve Oracle are not included in the ranking. This is the main difference in comparison with the results presented in the previous sections of this document. For each time series, the smallest normalized error produced by a competing method is written in red; the second smallest normalized error produced by a competing method is written in bold.
- Avg. represents the average of the normalized errors for the time series NSW, VIC and SA.
