COMPUTER SCIENCE

Principles of Programming

(Time Allowed: TWO hours)

NOTE:
You must answer all questions in this exam. No calculators are permitted. Answer in the space provided in this booklet. There is space at the back for answers which overflow the allotted space.

Question 1 (10 marks)

a) Complete the output produced by the following code.

```python
a = 2 * 3 ** 2 + 1 - 9 // 2 * 2
b = 4 % 10 * 10 % 5
print("a:", a, "b:", b)
```

```
a: b:
```

(2 marks)

b) Complete the output produced by the following code.

```python
words = "CHIT-CHAT"
index1 = words.find('T')
index2 = words.rfind('H')
letters = words[index1: index2]
print("Letters:", letters)
```

```
Letters:
```

(2 marks)

c) In the boxes below, assign integer values to the variable, value, so that the output when the code is executed is:

Yes
No

```python
value =
if len(str(value)) == 1 and (value % 5 == 0 or value % 4 == 0):
    print("Yes")
else:
    print("No")
```

```python
value =
if len(str(value)) == 1 and (value % 5 == 0 or value % 4 == 0):
    print("Yes")
else:
    print("No")
```

(2 marks)
d) Complete the first assignment statement in the code below so that the output of the code is:

\[
\text{Result: True}
\]

```python
a_string = "A B D"

a_list = a_string.split()
result = len(a_list) == 6 and a_list[1] == a_list[-2]
print("Result:", result)
```

(2 marks)

e) Complete the output produced by the following code.

```python
list1 = [1, 2, 5]
list2 = list1
list1.append(6)

tuple1 = (5, 7)
tuple2 = tuple1
tuple1 = tuple1 + (4, 6, 1)

print("1:", list1 == list2, "2:", tuple1 == tuple2)
```

```
1: True
2: True
```

(2 marks)
Question 2 (14 marks)

a) Complete the output produced when the following `main()` function is executed.

```python
def main():
    total = do_something([3, 4, 2, 6, 7, 1], 4)
    print("1:", total)
    print("2:", do_something([3, 4, 2, 6, 7, 1], 2))

def do_something(a_list, position):
    a_list.sort()
    total = 0
    for i in range(position, len(a_list)):
        total = total + a_list[i]
    return total
```

1:
2:  

(4 marks)

b) In the `main()` function below, complete the function call so that the output when the `main()` function is executed is:

Result: 6

```python
def main():
    a_list = [4, 3, 2, 6, 0, 1]
    result = do_something( )
    print("Result:", result)

def do_something(a_list, position):
    a_list.sort()
    total = 0
    for i in range(position, len(a_list)):
        total = total + a_list[i]
    return total
```

(4 marks)
c) Complete the `get_unique_code()` function below which returns a string which is made up of four unique random digits from 2 to 8 both inclusive. Note that the string which is returned must have a length of 4 and all four digits in the string must be unique.

**Note:** you can assume that the `random` module has been imported.

For example, executing the following `main()` function using the completed `get_unique_code()` function may give the output:

```
1. 7635
2. 3758
3. 6843
```

```python
def main():
    code = get_unique_code()
    print("1.", code)
    print("2.", get_unique_code())
    print("3.", get_unique_code())

def get_unique_code():
```

(6 marks)
Question 3 (12 marks)

a) Give the output produced when the following main() function is executed.

```python
def main():
    function_ifs(4, 6, 3)

def function_ifs(a, b, c):
    if a > b and c < b:
        print("A")
    elif not a < 5 and a > c:
        print("B")
    elif b < c or c < 5:
        print("C")
        if not a < 20:
            print("D")
        else:
            print("E")
            if a > b or c > b:
                print("F")
    if a >= 4:
        print("G")
    print("H")
```

(4 marks)

b) Give the output produced when the following code is executed.

```python
number = 10

while number > 3:
    if number % 3 == 0:
        number = number - 1
    print(number, end = " ")

number = number - 1

print(number)
```
c) Rewrite the following code using an equivalent `for ... in range()` loop instead of the `while` loop:

```python
num = 34
count = 0
while num >= 10:
    print(num)
    count = count + 1
    num = num - 5
```
Question 4 (15 marks)

a) In the boxes below, show each element of `a_list` after the following code has been executed. Use as many of the boxes as you need.

```python
a_list = [5, 3, 1, 8, 2, 4]
a_list.insert(2, 8)
value = a_list.pop(1)
a_list.insert(4, value)
value = a_list.pop()
value = value * a_list.index(3)
a_list.append(value)
```

b) Complete the output produced when the following `main()` function is executed.

```python
def main():
a_list = [4, 3, 2, 9, 2, 7, 8, 3, 2, 8]
count = 0
for index in range(len(a_list)):
    num = a_list[index]
    if num in a_list[index + 1:]:
        count = count + 1

print("Count:", count)
```

Count:
c) Complete the `get_funny_sum()` function which is passed two list parameters of exactly the same length. The first parameter is a list of integers and the second parameter is a list of booleans. The function returns a "total" which is obtained in the following way:

   Each value of the list of integers is added to the total if the corresponding boolean is `True` and it is subtracted from the total if the corresponding boolean is `False`.

For example, executing the following `main()` function using the completed function gives the output:

   ```python
   Total: 9
   ```

   ```python
def main():
    a_list = [4, 2, 1, 5, 3]
    add_or_subtract = [True, False, False, True, True]
    total = get_funny_sum(a_list, add_or_subtract)
    print("Total:", total)

def get_funny_sum(numbers, plus_minus):
```

(6 marks)
Question 5 (9 marks)

a) Complete the output produced when the following `main()` function is executed.

```python
def main():
    a_list = [3, 4, 7]
    do_something1(a_list)
    print("a_list:", a_list)

def do_something1(list1):
    list2 = list1
    extra_list = [4, 5]
    for element in extra_list:
        list2.append(element)

    a_list: [
```

```

(2 marks)
```

b) Give the output produced when the following `main()` function is executed.

```python
def main():
    a_list = [3, 7]
    do_something2(a_list)
    print("a_list:", a_list)

def do_something2(list1):
    list2 = [4, 6, 2]
    for element in list1:
        list2.insert(2, element)
    print("list2:", list2)
    list1 = list2
```

```

(2 marks)
```
c) Given the following code, what is the type of each of the three Python objects (object1, object2 and object3)?

```python
a_list = [1, 6, "four"]
a_tuple = (3, "funny", True)
a_dict = {"funny": (3, 5), "odd": (2, 1)}

object1 = a_list.pop(1)
object2 = a_tuple[a_list[0]]
object3 = a_dict[a_tuple[1]]
```

object1 is of type:
object2 is of type:
object3 is of type:

(3 marks)

d) The following function contains a docstring. In the docstring, add one doctest which does not fail.

```python
def do_a_check(value1, value2, value3):
    """Checks the parameter values
    """
    number = int(value1[value2])
    return number == value3
```

import doctest
doctest.testmod()

(2 marks)
Question 6 (15 marks)

Initial Note: a synonym is a word which has the same or nearly the same meaning as another word.

The following program reads information from the "WordsAndSynonyms.txt" file, processes the information and writes a simpler version of the information to the "SingleSynonym.txt" file.

Each line of the input file is made up of a word followed by one or more synonyms of the word separated by commas, e.g.,

"Amazing, incredible, unbelievable, fabulous, wonderful"

Below is an example of a "WordsAndSynonyms.txt" file (on the left) and the corresponding "SingleSynonym.txt" file (on the right) produced by the completed program:

![Screen shot of example output files](image)

a) Complete the get_word_synonyms_list() function which is passed one parameter: the name of a file containing words and their synonyms. Each line of the input file is one word followed by one or more synonyms separated by commas. The function returns a sorted list of strings. Each element of the returned list corresponds to each line of the input file all in lowercase characters and should not contain any newline characters.

b) Complete the remove_extra_synonyms() function which is passed a list of strings as a parameter. Each element of the parameter list is made up of a word followed by one or more synonyms of the word, separated by commas. This function changes the string elements of the parameter list so that each element is a tuple made up of the first word followed by the first synonym, e.g., the element:

"amazing, incredible, unbelievable, fabulous, wonderful" becomes the tuple ("amazing", "incredible").

The first two lines of this function have been completed for you.

c) Complete the write_to_file() function which has two parameters: the name of the output file and a list of tuples where each tuple contains two string elements: one word followed by one synonym. This function writes a numbered list of the word from each parameter list tuple followed by " = " followed by the synonym. Note that each number is followed by the string ". " See the screenshot of the example output file above on the right.
def main():
    filename = "WordsAndSynonyms.txt"
    words_and_synonyms = get_word_synonyms_list(filename)
    remove_extra_synonyms(words_and_synonyms)
    write_to_file("SingleSynonym.txt", words_and_synonyms)

def get_word_synonyms_list(filename):
    

def remove_extra_synonyms(words_and_synonyms):
    for i in range(len(words_and_synonyms)):
        single_string = words_and_synonyms[i]

def write_to_file(filename, words_and_synonyms):
    main() (15 marks)
Question 7 (15 marks)

a) Complete the following `main()` function which changes the `a_dict` dictionary in the following way:

Any corresponding values which are greater than their key are changed to the same number as the key,

e.g., if the key: value pair is 6: 8 then this pair becomes 6: 6, if the key: value pair is 6: 3 then this pair is left unchanged. The output of the completed code is:

```
Dictionary: {9: 9, 3: 3, 4: 4, 5: 5, 7: 2}
```

```
def main():
a_dict = {9: 12, 3: 7, 4: 4, 5: 8, 7: 2}

    def main():
        a_dict = {9: 12, 3: 7, 4: 4, 5: 8, 7: 2}

    print("Dictionary:", a_dict)

(4 marks)
```

b) Complete the output produced when the following `main()` function is executed:

```
def main():
a_dict1 = {'A': 4, 'B': 6, 'V': 2, 'N': 3}
dict1_letters = list(a_dict1.keys())
dict1_letters.sort()
word = ""

    def main():
        a_dict1 = {'A': 4, 'B': 6, 'V': 2, 'N': 3}
        dict1_letters = list(a_dict1.keys())
        dict1_letters.sort()
        word = ""

    for letter in dict1_letters:
        value = a_dict1[letter]
        if value in a_dict2:
            word = word + a_dict2[value]
        else:
            word = word + "X"

    print("Word:", word)

Word:
```

(4 marks)
c) Complete the `get_dictionary()` function which is passed a list of strings as a parameter. Each string in the parameter list is made up of exactly three letters followed by one or more digits. The function returns a dictionary where:

- the keys are the **unique** strings obtained from the first three letters of the parameter list elements - these are the letter codes,

- the values corresponding to each letter code are a **sorted list** of all the integers which have the same first three letters. The integers are obtained by slicing the list element string from index 3 to the end of the string and then converting it into an integer.

For example, executing the following program with the completed function prints:

```python
{'stx': [766], 'pmd': [65, 651], 'abc': [213, 456, 8765]}
```

```python
def main():
    codes_list = ["abc8765", "pmd65", "abc456", "abc213",
                  "pmd651", "stx766"]
    a_dict = get_dictionary(codes_list)
    print(a_dict)

def get_dictionary(codes_list):
    main()
```

(7 marks)
**Question 8 (10 marks)**

Both parts a) and b) of this question refer to the following program:

```python
from tkinter import *

def draw_pattern(a_canvas):
    size = 10
    pattern_list = [(1, 4), (2, 3), (1, 3), (3, 6), (1, 2)]
    top = size
    for each_tuple in pattern_list:
        shape_type = each_tuple[0]
        how_many = each_tuple[1]
        left = size * shape_type
        for count in range(how_many):
            area = (left, top, left + size, top + size)
            if shape_type == 1:
                a_canvas.create_rectangle(area)
            elif shape_type == 2:
                a_canvas.create_oval(area, fill='black')
            elif shape_type == 3:
                a_canvas.create_line(left + size, top, left, top + size)
        left = left + size
        top = top + size

def main():
    root = Tk()
    root.title("A Canvas")
    root.geometry("125x85+10+10")
    a_canvas = Canvas(root, bg="white")
    a_canvas.pack(fill=BOTH, expand=1) # Canvas fills whole window
    draw_pattern(a_canvas)
    root.mainloop()

main()
```

a) In the above program, what kind of shape corresponds to a `shape_type` of 3?

(2 marks)
b) As accurately as possible, in the window below, show what is drawn by the above program. Grid lines have been drawn in the window to help you. The gap between adjacent gridlines is 10 pixels.
