Lecture 8 – More practice defining functions, functions can call other functions, the scope of variables
At the end of this lecture, students should be able to:

- write functions which perform a task
- understand that a function can call another function
- understand the scope of variable
- always use excellent function names and variable names to ensure that the purpose of the function is clear
Recap

From lecture 7

- functions which accept arguments and return values can be defined
- calls to functions which have been defined cause the code inside the function to be executed
- we must use excellent function names and variable names to ensure that the purpose of the function is clear
- each function performs one task

```python
def get_dice_total():
    dice1 = random.randrange(1, 7)
    dice2 = random.randrange(1, 7)
    return dice1 + dice2

def get_discount_price(price):
    discount_price = price * 0.95
    return discount_price

dice_throw = get_dice_total()
full_price = 345.67
final_price = get_discount_price(full_price)
```
A Python function has the following syntax:

```python
def function_name(comma_separated_parameters):
    statements in the function
    return value_to_be_returned
```

- **Function name**
- **Function parameters**
- **Colon**
- **Indentation** (either 1 tab or 4 spaces)
- **Return value**
- **Statements in the body of the function**
Functions with no return statement

If a function does not need to return a result, then an optional `return` statement can be used as the last statement of the function (see lines 4 and 8).

```python
1 def display_welcome(name):
2     message = "Welcome **" + name + "**"
3     print(message)
4     return

5 def display_cost(dollars, cents):
6     cost_str = "Cost is $" + str(dollars) + ":" + str(cents)
7     print(cost_str)
8     return

9 display_welcome("Sam")
10 print()
11 display_cost(15, 35)
```

Welcome **Sam**

Cost is $15:35
Functions with no return statement

If a function does not need to return a result, then the last statement (the return statement) can be omitted. The following program behaves in exactly the same way as the program on the previous slide.

```python
def display_welcome(name):
    message = "Welcome **" + name + "**"
    print(message)

def display_cost(dollars, cents):
    cost_str = "Cost is $" + str(dollars) + ":" + str(cents)
    print(cost_str)

display_welcome("Sam")
display_cost(15, 35)
```

Welcome **Sam**

Cost is $15:35
Functions with no return statement

In Python, functions which do not explicitly return any value, in fact return the value `None` by default.

```python
def display_welcome(name):
    message = "Welcome **" + name + "**"
    print(message)

def display_cost(dollars, cents):
    cost_str = "Cost is $" + str(dollars) + ":" + str(cents)
    print(cost_str)

print(display_welcome("Sam"))
print()
result = display_cost(15, 35)
print(result)
```

See slide 14 of lecture 4:

`None` is a special value which can be assigned to a variable and it means that the variable is not referencing (pointing to) any object.
Functions with no parameters

Functions may not need to have any parameters inside the round brackets. If the function does not need to receive any information in order to do its job then there will not be any parameters in its parameter list.

```python
def display_intro():
    message = "Game of Nim"
    print(message)

def display_menu():
    print("1. Option 1")
    print("2. Option 2")
    print("3. exit")

display_intro()
print()
display_menu()
```
Python programs are structured through indentation

• All programming languages use blocks of code and in all programming languages, it is desirable that blocks of code be indented (this is a style requirement, not a language requirement). This principle makes it easier to read and understand code.

• In Python, indentation of blocks of code is a language requirement not a matter of style. All statements belonging to the same block of code have the same indentation, i.e., the statements within a block line up vertically. The block ends at a less indented line or at the end of the program. If a block has to be more deeply nested, it is simply indented further to the right.

```python
import blah
n = blahblahblah
n = n + blahblahblah
blahblahblahblahblahblah:
    blahblahblah:
    c1 = blahblahblah
    c2 = blahblahblah
    blahblahblahblahblahblah:
        blahblahblah
        blahblahblah
print("The end")
```
Python code is structured through indentation. Below is a diagram showing the indentation of a Python program which contains no function definitions.
Python code is structured through indentation. Below is a diagram showing the indentation of a Python program which contains two function definitions.

```
def ....
  Function body

def ....
  Function body
```

```
Block 1
  Block 2
    Block 2 continued
  Block 3
    Block 2 continued
Block 1 continued
```

May have some import statements here

Two function definitions at the top of the program
Python – indentation and colons

The use of colons (:) is another aspect of Python program structure

• The statement marking the beginning of an indented block ends with a colon.

```python
def display_intro():
    message = "Game of Nim"
    print(message)

def display_winner_details(winner, score):
    message = "*** " + winner.upper() + " (" + str(score) + ")
    print(message)

display_intro()
print()
display_winner_details("Joe Li", 56)
```

Game of Nim

*** JOE LI (56) ***
Each statement marking the beginning of an indented block ends with a colon. Below is a diagram showing the indentation of a Python program which contains no function definitions.
Each statement marking the beginning of an indented block ends with a colon. Below is a diagram showing the indentation of a Python program which contains two function definitions.
Python – program execution

A Python program starts executing at the first unindented statement (line 7 in the code below).

When the Python interpreter comes across statements (other than def or import ... or a few other keywords) which are written in the left-most column of the program, it will start the program by executing these statements.

```python
def display_intro():
    message = "Game of Nim"
    print(message)

def display_winner_details(winner, score):
    message = "*** " + winner.upper() + " (" + str(score) + ") ***"
    print(message)

display_intro()
print()
display_winner_details("Jo Li", 56)
```

Game of Nim

*** JO LI (56) ***
The following program will execute without error but there is no output.

```python
1  def display_intro():
2      message = "Game of Nim"
3      print(message)

4  def display_winner_details(winner, score):
5      message = ("*** " + winner.upper() + " (" + str(score) + ") ***")
6      print(message)
```

The code in the two functions is looked at (parsed) by the interpreter. You can verify this: put an error into one part of the function code (e.g., put `print(message)` in line 6) and you will see that the interpreter will display the error.
Local variables and their scope

When you set the value of a variable inside a function, the Python interpreter creates a **local variable** with that name.

In the following example, the variables: `message`, `author`, `length` and `symbols` are local variables defined inside the `display_intro()` function.

In a function, **local variables** exist from the moment they are set (used) until the end of the function block inside which they are used. For example the variable, `author`, exists from line 3 to line 9.

```python
def display_intro():
    message = "Game of Nim"
    author = "by Adriana Ferraro"
    length = max(len(message), len(author))
    symbols = "*" * length
    print(symbols)
    print(message)
    print(author)
    print(symbols)

display_intro()
```

***************
Game of Nim
by Adriana Ferraro
***************
Variables – out of scope

When you try to use a variable which is **out of scope**, the interpreter will display an error message:

```python
def display_intro():
    message = "Game of Nim"
    author = "by Adriana Ferraro"
    length = max(len(message), len(author))
    symbols = "*" * length
    print(symbols)
    print(message)
    print(author)
    print(symbols)

display_intro()
print(author)
```

```
***************
Game of Nim
by Adriana Ferraro
***************
Traceback (most recent call last):
  File "OutOfScopeExample.py", line 11, in <module>
    print(author)
NameError: name 'author' is not defined
```
Complete the output of the following program.

```python
def display_intro():
    message = "Game of Nim by Adriana Ferraro"
    length = len(message)
    symbols = "*" * length
    print(symbols)
    print(message)
    print(symbols)

message = "bye bye!"
display_intro()
print(message)
```

```
 *************************
Game of Nim by Adriana Ferraro
 *************************
```

19
The scope of parameters

Parameters are the variables which are listed in the function header.

- The **scope of parameters** is the same as for local variables, i.e., they exist from the moment they are set (at the beginning of the function) to the end of the function block inside which they are listed, i.e., until the end of the function definition. In the example below the parameters, `winner` and `score`, exist from line 1 to line 4.

```python
1 def display_winner_details(winner, score):
2     message = "*** " + winner.upper() + " ("
3     message = message + str(score) + ") ***"
4     print(message)
5 display_winner_details("Joe Li", 56)

*** JOE LI (56) ***
```
Example with four function calls

```python
def get_winner_message(name):
    message = "*** Game of Nim: " + name + " is the winner ***"
    return message

def display_winner_details(score, winner_message):
    message = "(" + str(score) + " points)"
    number_of_blanks = (len(winner_message) - len(message))// 2
    blanks = " " * number_of_blanks
    print(winner_message)
    print(blanks + message)

message = get_winner_message("Sam")
display_winner_details(66, message)
print()  # intentionally added to separate the two winner messages
message = get_winner_message("Helen")
display_winner_details(178, message)
```
Functions can make calls to other functions

```python
# def get_winner_message(name):
message = "*** Game of Nim: " + name + " is the winner ***"
return message

# def display_winner_details(winner, score):
message = "(" + str(score) + " points)"
winner_message = get_winner_message(winner)
number_of_blanks = (len(winner_message) - len(message))// 2
blanks = " " * number_of_blanks
print(winner_message)
print(blanks + message)

display_winner_details("Sam", 66)
print()
display_winner_details("Helen", 178)
```
Exercise

Complete the `get_discount()` function which returns the discount amount (a float rounded to 2 decimal places). The function is passed two parameters, the amount and the discount rate (an integer %).

```python
def get_discount(amount, rate):
    discount_message = "Discount: $" + str(get_discount(234, 5))
    print(discount_message)
    discount_message = "Discount: $" + str(get_discount(125, 15))
    print(discount_message)
```

Discount: $11.7
Discount: $18.75
Exercise

Complete the `get_discount_message()` function which returns a string made up of the rate of discount, the string "% Discount: $", and the discount amount. The function has two parameters, the discount amount and the rate of discount (a number).

```python
def get_discount_message(discount, rate):
    discount_message = get_discount_message(11.7, 5)
    print(discount_message)
    discount_message = get_discount_message(98.55, 15)
    print(discount_message)
```

5% Discount: $11.7
15% Discount: $98.55
Exercise

Complete the print_docket() function which prints the sales docket information (the format should be as shown in the example output shown). The function is passed two arguments, the price and the discount rate (an int %). Your function code **MUST** make a call to both functions: get_discount() and get_discount_message().

```python
def get_discount(amount, rate):
    #code from slide 23

def get_discount_message(discount, rate):
    #code from slide 24

def print_docket(price, rate):

print_docket(234, 5)
print()
print_docket(657, 15)
```

Original price $234
5% Discount: $11.7
Price $222.3

Original price $657
15% Discount: $98.55
Price $558.45
Exercise

The following program prompts the user for a number of items to be packaged. Each box can hold 10 items. Any left over items require an extra box. The first 6 boxes cost $8 each and any boxes above the first 6, cost $5 each. The program executes as shown in the example outputs below. Design the functions needed to write this program and write the main code for this program.

Enter number of items: 20
Items: 20
Boxes needed: 2
Cost: $16

Enter number of items: 36
Items: 36
Boxes needed: 4
Cost: $32

Enter number of items: 65
Items: 65
Boxes needed: 7
Cost: $53

Enter number of items: 102
Items: 102
Boxes needed: 11
Cost: $73
Exercise

From the previous slide.

```python
#write the main code below
items_per_box = 10
```

Enter number of items: 102
Items: 102
Boxes needed: 11
Cost: $73
Show the errors

The following program has two errors. What are the errors? Write a correction for each error.

The desired output is shown below the program.

```python
def display_winner_details(winner, score):
    message = "*** " + winner.upper() + " (" + message = message + score + ") ***"
    print(message)

score = score + 50
display_winner_details("Joe Li", score)
print(score)
```

*** JOE LI (50) ***
50
In a Python program:

- functions can be used to perform various tasks
- a function can make calls to other functions
- the scope of variable needs to be understood
- It is important to always use excellent function names and variable names to ensure that the purpose of the function is clear
Examples of Python features used in this lecture

```python
def display_welcome(name):
    message = "Welcome **" + name + " **"
    print(message)
    return

def display_intro(name):
    local_variable = "Game of Nim"
    local_variable = local_variable + " by " + name
    print(local_variable)

def display_menu():
    print("1. Option 1")
    print("2. Option 2")
    print("3. exit")

display_menu()
display_welcome("Sam")
display_intro("Adriana Ferraro")
```
