## Python 2 - Conditionals and loops

Lecture 17 - COMPSCI111/111G S2 2019

- Recap of yesterday's lecture
, if statements
b while loops
- Introduced the IDLE IDE, variables
- Basic arithmetic operators
- Remainder (\%) operator
- print() function can be used to display text, arithmetic operations, variables etc.
- input () function allows you to capture the user's input from the keyboard
b int () converts the string value from input () into an integer
- float ( ) converts the string value from input ( ) into a floating point value
- int () and float () can also convert integers/floating point numbers to other data types
- Example:
$x=20.56$
print(int(x)) \#output is 20
- Example:
$y=10$
print(float(y)) \#output is 10.0

## IF statement

- Conditional activity (ie. 'if this then do that') is an important part of many programs
- The if statement lets you introduce conditional activity into your program
- Statements that are executed when if is true must be tabbed underneath the if statement
- Syntax:
if [logical condition]:
[lines of code here]
else:
[lines of code here]

fig: Flowchart for if ... else statement

## Example

- determine if a number is odd or even, and print out an appropriate message.

- A logical condition will either evaluate to true or false

| Meaning | Operator | Example |
| :--- | :---: | :---: |
| Less than | $<$ | $\mathbf{a}<\mathbf{b}$ |
| Less than or equal to | $<=$ | $\mathbf{a}<=\mathbf{b}$ |
| Greater than | $>$ | $\mathbf{a}>\mathbf{b}$ |
| Greater than or equal to | $>=$ | $\mathbf{a}>=\mathbf{b}$ |
| Equal to | $==$ | $\mathbf{a}==\mathbf{b}$ |
| Not equal to | $\mathbf{l}=$ | $\mathbf{a}!=\mathbf{b}$ |

## 429 Logical conditions

- You can combine logical conditions using the Boolean operators
- if a and b:
- If the test in a and b evaluate to true, then the logical condition will be true
b e.g.if $x>1$ and $y<2$
- if a or b:
- If either $a$ or $b$ evaluate to true, then the overall logical condition will be true
b e.g.if $x>1$ or $y<2$
- if not(a):
- Inverts the result of a
- e.g.if not(5>6)
- Write a program that asks the user to enter a number between I and IO (inclusive). The program will print out "Correct" if the number is in the range and "Incorrect" if the number is outside the range.
- Example output (bold text is the user's input):

Please enter a number (1-10): 34 Incorrect
Please enter a number (1-10): 6
Correct

Prompt the user for a number

Convert it to an integer

If between I and IO (inclusive)

- Print "Correct"

Else

- Print "Incorrect"

## IF statement example

number = int(input("Please enter a number (1-10): "))
if number >= 1 and number <= 10: print("Correct")
else:
print("Incorrect")

- Write a program that asks the user to enter a number. The program should determine if the number is odd or even, and print out an appropriate message.
- Example output (bold text is the user's input) :

Please enter a number: 56
You entered 56 which is even
Please enter a number: 33
You entered 33 which is odd

## 529 Algorithm:

Prompt the user for a number

Convert it to an integer

If it is an even number

- "You entered", $\qquad$ ,"which is even"

## Else

- "You entered", $\qquad$ "which is odd"
- Allows you to repeat certain statements for as long as the loop's logical condition evaluates to true
- Statements that are executed when the while's condition is true must be tabbed underneath the while statement
- Syntax:
while [logical condition]:
[lines of code here while condition is true]

## Example

- Write a program to print the numbers from I to 5 current = 1 while current <= 5:
print(current)
current = current + 1 print("Finished!")
- Output:

1
2
3
4
5
Finished!

## Exercise 2

- Write a program that repeatedly asks the user to enter a number between I and IO (inclusive). When they do so, the program should print "Well done" on the screen and end
- Example output (bold text is the user's input):

Enter a number between 1 and 10: 99
Enter a number between 1 and 10: -1
Enter a number between 1 and 10: 10 Well done

## Flow chart

## Exercise 3

- Write a program that repeatedly asks the user to enter a number. If the number is even, then " $x$ is even" (where $x$ is the number) should be printed on screen. If the number is odd, then " $x$ is odd" should be printed on screen. The program must print "Thanks" and end when the user types ' 0 '
- Example output (bold text is the user's input):

Please enter a number: 45
45 is odd
Please enter a number: 12
12 is even
Please enter a number: 0
Thanks

Flow chart
Please enter a number: 45 45 is odd Please enter a number:-12
12 is even
prompt the user for a number Please enter a number: 0 Thanks

## Summary

- if statements allow you to introduce conditional activities into your program
- while loops allow you to repeat certain statements for as long as the logical condition evaluates to true
