

ASYMPTOTICS OF COEFFICIENTS OF MULTIVARIATE GENERATING FUNCTIONS: IMPROVEMENTS FOR SMOOTH POINTS

ALEXANDER RAICHEV AND MARK C. WILSON

ABSTRACT. Let $\sum_{\beta \in \mathbb{N}^d} F_\beta x^\beta$ be a multivariate power series. For example $\sum F_\beta x^\beta$ could be a generating function for a combinatorial class. Assume that in a neighbourhood of the origin this series represents a nonentire function $F = G/H^p$ where G and H are holomorphic and p is a positive integer. Given a direction $\alpha \in \mathbb{N}_+^d$ for which the asymptotics are controlled by a smooth point of the singular variety $H = 0$, we compute the asymptotics of $F_{n\alpha}$ as $n \rightarrow \infty$. We do this via multivariate singularity analysis and give an explicit formula for the full asymptotic expansion. This improves on earlier work of R. Pemantle and the second author and allows for more accurate numerical approximation, as demonstrated by our examples.

1. INTRODUCTION

Let $\sum_{\beta \in \mathbb{N}^d} F_\beta x^\beta$ be a multivariate power series. For example $\sum F_\beta x^\beta$ could be a generating function for a combinatorial class. In [PW02, PW04] Pemantle and Wilson derived asymptotic expansions for the coefficients F_β as $\beta \rightarrow \infty$ for large classes of series that arise often in applications. In this article we further their program of asymptotics of coefficients of multivariate generating functions.

Assume that in a neighbourhood of the origin the power series $\sum_{\beta \in \mathbb{N}^d} F_\beta x^\beta$ is the Maclaurin series of a nonentire function $F = G/H^p$ where G and H are holomorphic and p is a positive integer. For example F could be a rational function. Using multivariate singularity analysis we derive the asymptotics of $F_{n\alpha}$ for $\alpha \in \mathbb{N}_+^d$ and $n \rightarrow \infty$ in the case that these asymptotics are controlled by smooth points of the singular variety $H = 0$.

Our presentation is organized as follows. In Section 2 we set our notation and basic definitions. In Section 3 we give two explicit formulas for all the terms in the asymptotic expansion of $F_{n\alpha}$. This improves upon [PW02] which gave formulas for the leading term only and only for the case $p = 1$. Furthermore, we prove that the expansions for $F_{n\alpha}$ are uniform in α as claimed in [PW02]. In Section 4 we go on to express our formulas in terms of the original data G and H for easier use in calculation. In Section 5 we apply our formulas to three combinatorial examples and demonstrate the greater numerical accuracy of many-term asymptotic expansions over single-term expansions. Lastly, in Section 6 we present the two theorems from analysis on Fourier-Laplace integrals that we use in our proofs.

2. NOTATION AND DEFINITIONS

Let \mathbb{N}_+ and \mathbb{R}_+ denote the set of positive natural numbers and positive real numbers, respectively. For $r \in \mathbb{R}$ and $k \in \mathbb{N} = \mathbb{N}_+ \cup \{0\}$ set $r^{\bar{k}} = r(r+1) \cdots (r+k-1)$, the k th rising factorial power of r , with the convention that $r^{\bar{0}} = 1$. For $m \in \mathbb{N}_+$, $x \in \mathbb{C}^m$, and

Key words and phrases. generating function, multivariate, asymptotics, higher-order terms.

$i \leq m$ let x_i denote component i of x and $\widehat{x} = (x_1, \dots, x_{m-1})$. For $\alpha \in \mathbb{N}_+^m$, $x \in \mathbb{C}^m$, and $n \in \mathbb{N}_+$ define $\alpha + 1 = (\alpha_1 + 1, \dots, \alpha_m + 1)$, $\alpha! = \alpha_1! \cdots \alpha_m!$, $n\alpha = (n\alpha_1, \dots, n\alpha_m)$, $x^\alpha = x_1^{\alpha_1} \cdots x_m^{\alpha_m}$, and $\partial^\alpha = \partial_1^{\alpha_1} \cdots \partial_m^{\alpha_m}$, where ∂_j is partial differentiation with respect to component j . For $c \in \mathbb{C}^m$ let $D(c) = \{x \in \mathbb{C}^m : \forall j \leq m |x_j| < |c_j|\}$ and $C(c) = \{x \in \mathbb{C}^m : \forall j \leq m |x_j| = |c_j|\}$, the polydisc and polycircle centred at the origin with polyradius $(|c_1|, \dots, |c_m|)$, respectively. Finally, all sum indices will begin at the zero tuple unless indicated otherwise.

Fix $d \in \mathbb{N}_+$ and let $G, H : \mathcal{D} \rightarrow \mathbb{C}$ be holomorphic functions on a polydisc $\mathcal{D} \subseteq \mathbb{C}^d$. Assume that G and H are relatively prime in the ring of holomorphic functions on \mathcal{D} . Let $p \in \mathbb{N}_+$ and define $F = G/H^p$. Then F is holomorphic on $\mathcal{D} \setminus \mathcal{V}$, where \mathcal{V} is the analytic variety $\{x \in \mathcal{D} : H(x) = 0\}$. By [Sch05, Example 4.1.5, Corollary 4.2.2] the variety \mathcal{V} has dimension $d - 1$ and $\mathcal{D} \setminus \mathcal{V}$ is a domain, that is, a nonempty open connected set. Assume $0 \in \mathcal{D} \setminus \mathcal{V}$ and $\mathcal{V} \neq \emptyset$. Let $\sum_{\beta \in \mathbb{N}^d} F_\beta x^\beta$ be the Maclaurin series of F , so $\partial^\beta F(0)/\beta! = F_\beta$ for all $\beta \in \mathbb{N}^d$.

We will derive asymptotics for F_β as $\beta \rightarrow \infty$ along straight lines through the origin and off the axes, that is, for $F_{n\alpha}$ with $\alpha \in \mathbb{N}_+^d$ and $n \rightarrow \infty$. For $d = 2$ and $\beta \rightarrow \infty$ along more general paths see [Lla06].

First we recall some key definitions from [PW02]. Just as in the univariate case, the asymptotics for the Maclaurin coefficients of F are determined by the location and type of singularities of F , that is, by the geometry of \mathcal{V} . Generally the singularities closest to the origin are the most important. We define ‘closest to the origin’ in terms of polydiscs.

Definition 2.1. Let $c \in \mathcal{V}$. We say that c is **minimal** if there is no point $x \in \mathcal{V}$ such that $|x_j| < |c_j|$ for all $j \leq d$. We say that c is **strictly minimal** if there is a unique $x \in \mathcal{V}$ such that $|x_j| \leq |c_j|$ for all j , namely $x = c$, and we say that c is **finitely minimal** if there are finitely many such values of x .

The variety \mathcal{V} always contains minimal points. To see this let $c \in \mathcal{V}$ and define $f : \mathcal{V} \cap \overline{D(c)} \rightarrow \mathbb{R}$ by $f(x) = \sqrt{x_1^2 + \cdots + x_d^2}$. Since f is a continuous function on a compact space, it has a minimum, and that minimum is a minimal point of \mathcal{V} .

We focus on the singularities of F with the simplest geometry, namely the regular or smooth points of \mathcal{V} . For a summary of what is known about non-smooth points see the survey [PW].

Definition 2.2. A point $c \in \mathcal{V}$ is called **smooth** if \mathcal{V} is a smooth complex manifold in a neighbourhood of c .

Equivalently, a point $c \in \mathcal{V}$ is smooth iff $\partial_j H(c) \neq 0$ for some j iff c_j is a zero of order one of $z \mapsto H(c_1, \dots, c_{j-1}, z, c_{j+1}, \dots, c_d)$ for some j . See [BK86, page 363] for a proof of the first equivalence.

We will approximate $F_{n\alpha}$ with integrals and, in so doing, will need to consider the singularities of F relevant to α . These singularities are called critical points. For a more geometric explanation of their relevance and the stratified Morse theory behind it see [PW].

Definition 2.3. Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$ be a smooth point. We say that c is **critical** for α if it is a solution of the system of $d - 1$ equations

$$\alpha_1^{-1} x_1 \partial_1 H(x) = \dots = \alpha_d^{-1} x_d \partial_d H(x).$$

We say c is **isolated** for α if, in addition, it has a neighbourhood in which it is the only critical point for α .

When H is a polynomial, the system of d equations in d unknowns given by $H(x) = 0$ and the critical point equations generally has a finite set of solutions.

Remark 2.4. At times it will be convenient to work in projective space. Recall that \mathbb{CP}^{d-1} is the set of equivalence classes of $\mathbb{C}^d \setminus \{0\}$ under the equivalence relation \sim given by $x \sim x'$ iff $x = \lambda x'$ for some $\lambda \in \mathbb{C} \setminus \{0\}$. Let $\bar{\cdot} : \mathbb{C}^d \setminus \{0\} \rightarrow \mathbb{CP}^{d-1}$ be the natural map which takes a point x to its equivalence class $[x]$.

While the definition of $F_{n\alpha}$ only makes sense for $\alpha \in \mathbb{N}^d$, the definition of critical point is well-defined for all $\alpha \in \mathbb{CP}^{d-1}$ with at least one nonzero component.

3. THE FULL ASYMPTOTIC EXPANSION

Pemantle and Wilson [PW02] showed that if $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$ is strictly minimal, smooth, critical and isolated for α , and nondegenerate (which we will define shortly), then there exist $b_k \in \mathbb{C}$ such that for all $N \in \mathbb{N}_+$ one has the asymptotic expansion

$$F_{n\alpha} = c^{-n\alpha} \left[\sum_{k < N} b_k n^{-(d-1)/2-k} + O(n^{-(d-1)/2-N}) \right]$$

as $n \rightarrow \infty$. They also derived a similar expansion for degenerate points in the case $d = 2$ and gave an explicit formula for b_0 for all d when $p = 1$.

In this section we derive explicit formulas for all b_k and all p . To formulate our results we employ the following functions.

Definition 3.1. Let $c \in \mathcal{V}$ be smooth, and assume without loss of generality that $\partial_d H(c) \neq 0$. By the implicit function theorem there exists a bounded neighborhood W of \hat{c} and a holomorphic function h on W such that $(w, h(w)) \in \mathcal{V}$, $\partial_d H(w, h(w)) \neq 0$ for all $w \in W$, and $h(\hat{c}) = c_d$. Suppose $c_d \neq 0$, so that we may also assume that h is nonzero on W .

For $j < p$ define $u_j : W \rightarrow \mathbb{C}$, $E : [-1, 1]^{d-1} \rightarrow \mathbb{C}^{d-1}$, and $\tilde{u}_j, \tilde{h} : E^{-1}(W \cap C(c)) \rightarrow \mathbb{C}$ by

$$\begin{aligned} u_j(w) &= \lim_{y \rightarrow h(w)} (-y)^{-p+j} \frac{\partial^j}{\partial y^j} \left((y - h(w))^p F(w, y) \right), \\ E(t) &= (c_1 e^{it_1}, \dots, c_{d-1} e^{it_{d-1}}), \\ \tilde{u}_j &= u_j \circ E \\ \tilde{h} &= h \circ E. \end{aligned}$$

Furthermore, for c critical for α define $\tilde{g} : E^{-1}(W) \rightarrow \mathbb{C}$ by

$$\tilde{g}(t) = \log \left(\frac{\tilde{h}(t)}{\tilde{h}(0)} \right) + i \sum_{1 \leq m < d} \frac{\alpha_m}{\alpha_d} t_m.$$

Then \tilde{g} is well-defined for any $\alpha \in \mathbb{CP}^{d-1}$ with $\alpha_d \neq 0$ since \tilde{g} does not depend on the magnitude of α and since h is nonzero on W . Moreover, \tilde{u}_j, \tilde{h} , and \tilde{g} are all C^∞ functions.

If $\det \tilde{g}''(0) \neq 0$, then c is called **nondegenerate**.

In the context of a single pair of appropriate c and α we will use the functions of Definition 3.1 without further introduction.

Now for the first theorem.

Theorem 3.2. Let $d \geq 2$ and $\alpha \in \mathbb{N}_+^d$. If $c \in \mathcal{V}$ is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, critical and isolated for α , and nondegenerate, then for all $N \in \mathbb{N}$,

$$(\clubsuit) \quad F_{n\alpha} = c^{-n\alpha} \left[\left((2\pi\alpha_d n)^{d-1} \det \tilde{g}''(0) \right)^{-1/2} \sum_{j \leq p-1} \sum_{k < N} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} (\alpha_d n)^{-k} L_k(\tilde{u}_j, \tilde{g}) + O(n^{p-1-(d-1)/2-N}) \right]$$

as $n \rightarrow \infty$.

Here

$$L_k(\tilde{u}_j, \tilde{g}) = \sum_{l \leq 2k} \frac{\mathcal{H}^{l+k}(\tilde{u}_j \tilde{g}^l)(t_0)}{(-1)^k 2^{l+k} l! (l+k)!},$$

$\tilde{g}(t) = \tilde{g}(t) - \tilde{g}(t_0) - \frac{1}{2}(t-t_0)\tilde{g}''(t)(t-t_0)^T$, \mathcal{H} is the differential operator $-\sum_{r,s} (\tilde{g}''(t_0)^{-1})_{r,s} \partial_r \partial_s$, and $t_0 = 0$. In every term of $L_k(\tilde{u}_j, \tilde{g})$ the total number of derivatives of \tilde{u} and of \tilde{g}'' is at most $2k$.

In the case $d = 2$ we can drop the nondegeneracy hypothesis.

Theorem 3.3. Let $d = 2$ and $\alpha \in \mathbb{N}_+^d$. If $c \in \mathcal{V}$ is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, critical and isolated for α , and $v \geq 2$ is least such that $\tilde{g}^{(v)}(0) \neq 0$, then for all $N \in \mathbb{N}$,

$$(\spadesuit 0) \quad F_{n\alpha} = c^{-n\alpha} \left[\frac{(a\alpha_d n)^{-1/v}}{\pi v} \sum_{j < p} \sum_{k < N} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} (\alpha_d n)^{-2k/v} L_k^{\text{even}}(\tilde{u}_j, \tilde{g}) + O(n^{p-1-(2N+1)/v}) \right],$$

as $n \rightarrow \infty$ for v even and

$$(\spadesuit 1) \quad F_{n\alpha} = c^{-n\alpha} \left[\frac{(|a|\alpha_d n)^{-1/v}}{2\pi v} \sum_{j < p} \sum_{k < N} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} (\alpha_d n)^{-k/v} L_k^{\text{odd}}(\tilde{u}_j, \tilde{g}) + O(n^{p-1-(N+1)/v}) \right],$$

as $n \rightarrow \infty$ for v odd.

Here

$$L_k^{\text{even}}(\tilde{u}_j, \tilde{g}) = \sum_{l \leq 2k} \frac{(-1)^l \Gamma(\frac{2k+vl+1}{v})}{l! (2k+vl)!} \left(a^{-1/v} \frac{d}{dt} \right)^{2k+vl} (\tilde{u}_j \tilde{g}^l)(t_0),$$

$$L_k^{\text{odd}}(\tilde{u}_j, \tilde{g}) = \sum_{l \leq k} \frac{(-1)^l \Gamma(\frac{k+vl+1}{v})}{l! (k+vl)!} (\zeta^{k+vl+1} + (-1)^{k+vl} \zeta^{-(k+vl+1)})$$

$$\times \left(|a|^{-1/v} i \operatorname{sgn} a \frac{d}{dt} \right)^{k+vl} (\tilde{u}_j \tilde{g}^l)(t_0),$$

$\tilde{g}(t) = \tilde{g}(t) - \tilde{g}(t_0) - a(t - t_0)^v$, $a = \tilde{g}^{(v)}(t_0)/v!$, $\zeta = e^{i\pi/(2v)}$, and $t_0 = 0$. In every term of $L_k^{\text{even}}(u, g)$ the total number of derivatives of u and $g^{(v)}$ is at most $2k$, and in $L_k^{\text{odd}}(u, g)$ at most k .

In the formulas above we take $z^{-1/v} = |z|^{-1/v} e^{-i \arg z/v}$ for $z \in \mathbb{C} \setminus \{0\}$ with $\arg z \in [-\pi/2, \pi/2]$.

To prove Theorems 3.2 and 3.3 we follow the same general approach as in [PW02] and summarized in the following steps: (1) use Cauchy's integral formula and strict minimality to express $c^{n\alpha} F_{n\alpha}$ as a d -variate contour integral over a contour almost touching c ; (2) expand the contour across c and use Cauchy's residue theorem along with the smoothness of c to express the innermost integral as a residue; (3) calculate the residue explicitly, and take the resulting $(d - 1)$ -variate contour integral and change to real coordinates to get a Fourier-Laplace integral; (4) use theorems from analysis (see Section 6) to approximate the integral asymptotically.

Lemma 3.4 ([PW02, proof of Lemma 4.1], **Steps 1 & 2**). Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$. If c is strictly minimal and smooth with $c_d \partial_d H(c) \neq 0$, then there exists $\epsilon \in (0, 1)$ and a polydisc neighborhood D of \hat{c} such that

$$F_{n\alpha} = (2\pi i)^{1-d} \int_X \frac{-R(w)}{w^{n\hat{\alpha}+1}} dw + O(\epsilon^n)$$

as $n \rightarrow \infty$, where $X = D \cap C(\hat{c})$ and $R(w)$ is the residue of $y \mapsto F(w, y)y^{-\alpha_d n - 1}$ at $h(w)$. \square

Lemma 3.5 (Step 3). In the previous lemma,

$$R(w) = - \sum_{j < p} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} h(w)^{-\alpha_d n} u_j(w).$$

Thus

$$c^{n\alpha} F_{n\alpha} = (2\pi)^{1-d} \sum_{j < p} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} \int_{\tilde{X}} \tilde{u}_j(t) e^{-\alpha_d n \tilde{g}(t)} dt + O(\epsilon^n),$$

as $n \rightarrow \infty$, where $\tilde{X} = E^{-1}(X)$.

Proof. This is a straightforward calculation. Let $w \in X$. Since c is smooth, $h(w)$ is a simple zero of $y \mapsto H(w, y)$ and so a pole of order p of $y \mapsto F(w, y)$. Since h is nonzero on W , $h(w)$ is also a pole of order p of $y \mapsto F(w, y)y^{-\alpha_d n - 1}$. Thus

$$\begin{aligned} R(w) &= \lim_{y \rightarrow h(w)} \frac{1}{(p-1)!} \left(\frac{\partial}{\partial y} \right)^{p-1} \left((y - h(w))^p F(w, y) y^{-\alpha_d n - 1} \right) \\ &= - \frac{1}{(p-1)!} \lim_{y \rightarrow h(w)} \sum_{j < p} \binom{p-1}{j} \left(\frac{\partial}{\partial y} \right)^j \left((y - h(w))^p F(w, y) \right) \\ &\quad \times (\alpha_d n + 1)^{\overline{p-1-j}} (-1)^{p-j} y^{-\alpha_d n - p + j} \\ &= - \sum_{j \leq p-1} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} h(w)^{-\alpha_d n} \lim_{y \rightarrow h(w)} (-y)^{-p+j} \left(\frac{\partial}{\partial y} \right)^j \left((y - h(w))^p F(w, y) \right), \end{aligned}$$

from which the first identity follows by definition of u_j . Thus

$$\begin{aligned}
& c^{n\alpha}(2\pi i)^{1-d} \int_X \frac{-R(w)}{w^{n\hat{\alpha}+1}} dw \\
&= c^{n\alpha}(2\pi i)^{1-d} \int_X \frac{1}{w^{n\hat{\alpha}+1}} \sum_{j \leq p-1} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)!j!} h(w)^{-n\alpha_d} u_j(w) dw \\
&= (2\pi i)^{1-d} \sum_{j \leq p-1} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)!j!} \int_X \frac{\widehat{c}^{n\hat{\alpha}}}{w^{n\hat{\alpha}}} u_j(w) \left(\frac{h(w)}{h(\widehat{c})} \right)^{-\alpha_d n} \frac{dw}{\prod_{1 \leq m < d} w_m} \\
&= (2\pi)^{1-d} \sum_{j \leq p-1} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)!j!} \int_{\tilde{X}} \prod_{1 \leq m < d} e^{-i\alpha_m n t_m} \tilde{u}_j(t) \left(\frac{\tilde{h}(t)}{\tilde{h}(0)} \right)^{-\alpha_d n} dt \\
&\quad (\text{via the change of variables } w = E(t)) \\
&= (2\pi)^{1-d} \sum_{j < p} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)!j!} \int_{\tilde{X}} \tilde{u}_j(t) e^{-\alpha_d n \tilde{g}(t)} dt,
\end{aligned}$$

which with Lemma 3.4 proves the stated formula for $c^{n\alpha} F_{n\alpha}$. \square

Remark 3.6. In the case $d = 1$ Lemma 3.5 simplifies: h , u_j , and R become 0-ary functions, that is, constants (h becomes c), and there is no integral. Thus we arrive at the following known result.

If $c \in \mathcal{V}$ is strictly minimal and smooth, then there exists $\epsilon \in (0, 1)$ such that

$$F_n = c^{-n} \left[\sum_{j < p} \frac{(n+1)^{\overline{p-1-j}}}{(p-1-j)!j!} u_j + O(\epsilon^n) \right],$$

as $n \rightarrow \infty$, where

$$u_j = \lim_{x \rightarrow c} (-x)^{-p+j} \left(\frac{\partial}{\partial x} \right)^j \left((x-c)^p F(x) \right).$$

Moreover, if $c \in \mathcal{V}$ is finitely minimal and smooth and every point of $\mathcal{V} \cap C(c)$ is smooth, then the asymptotic expansion of F_n is the sum of the expansions around each point of $\mathcal{V} \cap C(c)$.

Before proceeding to Step 4 we collect a few technical facts about \tilde{g} .

Lemma 3.7. Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$. If c is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, and critical and isolated for α , then for all $t \in \tilde{X}$ we have $\Re \tilde{g}(t) \geq 0$ with equality only at $t = 0$ and $\tilde{g}'(t) = 0$ iff $t = 0$.

Proof. Firstly, $\tilde{g}(0) = 0$ by definition. Secondly, $\Re \tilde{g}(t) \geq 0$ with equality only at 0 since c is strictly minimal. Lastly, by the implicit function theorem, $\partial_m h(w) = -\partial_m H(w, h(w)) / \partial_d H(w, h(w))$ for all $m < d$ and $w \in W$. So for $t \in \tilde{X}$ we have

$$\partial_m \tilde{g}(t) = -i c_m e^{it_m} \frac{1}{h(E(t))} \frac{\partial_m H(E(t), h(E(t)))}{\partial_d H(E(t), h(E(t)))} + i \frac{\alpha_m}{\alpha_d}.$$

Therefore $\tilde{g}'(t) = 0$ iff

$$\alpha_m^{-1} c_m e^{it_m} \partial_m H(E(t), h(E(t))) = \alpha_d^{-1} h(E(t)) \partial_d H(E(t), h(E(t)))$$

for all $m < d$ iff $(E(t), h(E(t)))$ is critical for α iff $t = 0$ since c is isolated for α . \square

Proof of Theorem 3.2 (Step 4). By Lemmas 3.4 and 3.5 there exists $\epsilon \in (0, 1)$ and an open bounded neighbourhood \tilde{X} of 0 such that

$$c^{n\alpha} F_{n\alpha} = (2\pi)^{1-d} \sum_{j < p} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} I_{j,n} + O(\epsilon^n)$$

as $n \rightarrow \infty$, where $I_{j,n} = \int_{\tilde{X}} \tilde{u}_j(t) e^{-\alpha_d n \tilde{g}(t)} dt$.

Choose $\kappa \in C_c^\infty(\tilde{X})$ such that $\kappa = 1$ on a neighbourhood Y of 0. Then

$$I_{j,n} = \int_{\tilde{X}} \kappa(t) \tilde{u}_j(t) e^{-\alpha_d n \tilde{g}(t)} dt + \int_{\tilde{X}} (1 - \kappa(t)) \tilde{u}_j(t) e^{-\alpha_d n \tilde{g}(t)} dt.$$

The second integral decreases exponentially as $n \rightarrow \infty$ since $\Re \tilde{g}$ is strictly positive on the compact set $\tilde{X} \setminus Y$ by Lemma 3.7. By Lemma 3.7 again and our nondegeneracy hypothesis, we may apply Theorem 6.1 with $t_0 = 0$ to the first integral. Noting that $L_k(\kappa \tilde{u}_j, \tilde{g}) = L_k(\tilde{u}_j, \tilde{g})$ because the derivatives are evaluated at 0 and $\kappa = 1$ in a neighbourhood of 0, this gives

$$\begin{aligned} I_{j,n} &= e^{-n_d \tilde{g}(0)} \left(\det \left(\frac{\alpha_d n \tilde{g}''(0)}{2\pi} \right) \right)^{-1/2} \sum_{k < N} (\alpha_d n)^{-k} L_k(\tilde{u}_j, \tilde{g}) + O((\alpha_d n)^{-(d-1)/2-N}) \\ &= \left(\frac{\alpha_d n}{2\pi} \right)^{-(d-1)/2} (\det \tilde{g}''(0))^{-1/2} \sum_{k < N} (\alpha_d n)^{-k} L_k(\tilde{u}_j, \tilde{g}) + O(n^{-(d-1)/2-N}) \end{aligned}$$

as $n \rightarrow \infty$. Hence

$$\begin{aligned} c^{n\alpha} F_{n\alpha} &= (2\pi)^{1-d} \sum_{j < p} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} I_{j,n} + O(\epsilon^n) \\ &= \sum_{j < p} \sum_{k < N} \frac{(\alpha_d n + 1)^{\overline{p-1-j}}}{(p-1-j)! j!} \left((2\pi \alpha_d n)^{d-1} \det \tilde{g}''(0) \right)^{-1/2} (\alpha_d n)^{-k} L_k(\tilde{u}_j, \tilde{g}) \\ &\quad + O(n^{p-1-(d-1)/2-N}), \end{aligned}$$

as $n \rightarrow \infty$, as desired. \square

The proof of Theorem 3.3 is similar but uses Theorem 6.2 instead of Theorem 6.1.

In the case of finitely minimal points of \mathcal{V} we simply take an open set W for each finitely minimal point so that W contains no other finitely minimal points, repeat the proofs above for each such W , and add the asymptotic expansions. Thus we have the following.

Corollary 3.8. Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$. If c is finitely minimal and every point of $\mathcal{V} \cap C(c)$ satisfies the hypotheses (excluding strict minimality) of Theorem 3.2 or Theorem 3.3, then the asymptotic expansion of $F_{n\alpha}$ equals the sum of the expansions around each point of $\mathcal{V} \cap C(c)$. \square

Finally, we show that the asymptotic formulas for $F_{n\alpha}$ are uniform in α . This was claimed without proof in [PW02].

Proposition 3.9. Let $d \geq 2$ and $K \subseteq \mathbb{RP}^{d-1}$ be compact. Suppose that for all $\alpha \in K$ there exists a unique $c \in \mathcal{V}$ that is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, critical and isolated for α , and nondegenerate. Suppose that all these points c lie in a bounded open set $V \subset \mathcal{V}$ such that $x_d \partial_d H(x) \neq 0$ for all $x \in V$. Then for each $N \in \mathbb{N}$ the big-oh constant of \clubsuit stays bounded as $\alpha \in \mathbb{N}_+$ varies and $\bar{\alpha}$ stays in K .

Proposition 3.10. Let $d = 2$ and $K \subseteq \mathbb{R}\mathbb{P}^1$ be compact. Suppose there exists $v \geq 2$ such that for all $\alpha \in K$ there exists a unique $c \in \mathcal{V}$ that is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, critical and isolated for α , and v is the least integer greater than 2 such that $g^{(v)}(0) \neq 0$. Suppose that all these points c lie in a bounded open set $V \subset \mathcal{V}$ such that $x_d \partial_d H(x) \neq 0$ for all $x \in V$. Then for each $N \in \mathbb{N}$ the big-oh constant of $(\spadesuit 0)$ and $(\spadesuit 1)$ stays bounded as $\alpha \in \mathbb{N}_+$ varies and $\bar{\alpha}$ stays in K .

Proof of Proposition 3.9. We take up where the proof of Theorem 3.2 left off. Recall that \tilde{g} depends on α . Let us emphasize this dependence by writing \tilde{g}_α . By Theorem 6.1 it suffices to show that for any fixed positive integer P there exists $M > 0$ such that for all $\alpha \in K$ and all $\beta \in \mathbb{N}^{d-1}$ with $|\beta| \leq P$ we have

$$(\heartsuit) \quad \|\partial^\beta \tilde{g}_\alpha\|_\infty = \sup\{|\partial^\beta \tilde{g}_\alpha(t)| : t \in \tilde{X}\} \leq M,$$

where $\tilde{X} \subset \mathbb{R}^{d-1}$ is a suitable neighborhood of 0.

To prove such a bound we first show that the correspondence between a direction in K and its critical point is continuous. To this end it will be helpful to introduce the logarithmic Gauss map $\gamma : V \rightarrow \mathbb{C}\mathbb{P}^{d-1}$ defined by $x \mapsto [x_1 \partial_1 H(x), \dots, x_d \partial_d H(x)]$. Note that γ is well-defined since $(x_1 \partial_1 H(x), \dots, x_d \partial_d H(x)) \neq 0$ on V by hypothesis. Note also that $\alpha \in K$ is critical for c iff $\gamma(c) = \alpha$.

Since H is holomorphic on V , each $\partial_j H$ is holomorphic on V , so that γ is continuous. By hypothesis, for every $\alpha \in K$ the preimage $\gamma^{-1}(\{\alpha\})$ contains exactly one element. Thus $\gamma^{-1} : K \rightarrow V$ is well-defined. Moreover γ^{-1} is continuous since γ restricted to $\gamma^{-1}(K)$ is a continuous bijection on a compact space into a Hausdorff space and therefore a homeomorphism.

Each $\alpha \in K$ has associated to it a point $\gamma^{-1}(\alpha) \in \gamma^{-1}(K)$ which has associated to it the functions of Definition 3.1. We now show that finitely many such functions will do to handle all points of $\gamma^{-1}(K)$. For each $c \in \gamma^{-1}(K)$ let D be the polydisc from Lemma 3.4 containing \hat{c} and h the nonzero holomorphic function on D associated to c . Let D' be a polydisc such that $D' \subset \overline{D'} \subset D$. The collection of all such $D' \times h(D')$ forms an open cover for the compact space $\gamma^{-1}(K)$. So this cover has a finite subcover $D'_1 \times h_1(D'_1), \dots, D'_l \times h_l(D'_l)$. Let D_1, \dots, D_l be the superpolydiscs corresponding to D'_1, \dots, D'_l . To handle the various E of Definition 3.1, define $e : \prod_{j \leq l} \overline{D'_j} \times [-1, 1]^{d-1} \rightarrow \mathbb{C}^{d-1}$ by $(w, t) \mapsto (w_1 e^{it_1}, \dots, w_{d-1} e^{it_{d-1}})$. Then e is continuous, and for all j the open set $e^{-1}(D_j)$ contains $\overline{D'_j} \times \{0\}$. Since $\overline{D'_j}$ is compact, by the tube lemma [Mun75, Lemma 5.8] there exists a neighborhood Y_j of 0 in $[-1, 1]^{d-1}$ such that $e^{-1}(D_j) \supseteq \overline{D'_j} \times Y_j$. Set $Y = \bigcap_{j \leq l} Y_j \subset [-1, 1]^{d-1}$, and let \tilde{X} be a neighborhood of 0 with $\tilde{X} \subset \overline{\tilde{X}} \subset Y$. Thus to each $\alpha \in K$ are associated some $c = \gamma^{-1}(\alpha)$, D'_j , h_j , \tilde{h}_j , and $\log\left(\frac{\tilde{h}_j(t)}{\tilde{h}_j(0)}\right) + i \sum_{m < d} \frac{\alpha_m}{\alpha_d} t_m = \tilde{g}_\alpha$, where the last two functions are defined on Y_j and so on Y .

With this setup we now show (\heartsuit) . Since $A_j : Y \rightarrow \mathbb{R}$ for $j \leq l$ and $B : K \times Y \rightarrow \mathbb{R}$ defined by $A_j(t) = \left| \log\left(\frac{\tilde{h}_j(t)}{\tilde{h}_j(0)}\right) \right|$ and $B(\alpha, t) = \left| \sum_{m < d} \frac{\alpha_m}{\alpha_d} t_m \right|$ are continuous and \tilde{X} and K are compact, we have that $M_A := \sum_{j \leq l} \max\{A_j(t) : t \in \tilde{X}\} < \infty$, $M_B := \max\{B(\alpha, t) : \alpha \in K, t \in \tilde{X}\} < \infty$, and

$$\|\tilde{g}_\alpha\|_\infty \leq \sup_{\alpha \in K, t \in \tilde{X}} A_j(t) + B(\alpha, t) \quad (\text{for some } j \leq l) \leq M_A + M_B,$$

a bound that is independent of α . Similarly, since each \tilde{h}_j is C^∞ over Y , each $\|\partial^\beta \tilde{g}_\alpha\|_\infty$ for $|\beta| \leq P$ stays bounded as α varies within K , as desired. \square

The proof of Theorem 3.10 is similar but uses Theorem 6.2 instead of Theorem 6.1.

4. REWRITING THE EXPANSION IN TERMS OF THE ORIGINAL DATA

To actually compute with the formulas in Theorems 3.2 and 3.3 it is helpful to rewrite the quantities involved in terms of the original data G and H . The propositions below give formulas for calculating $\tilde{g}''(0)$ and u_j in terms of derivatives of G and H .

Proposition 4.1 ([RWa, Theorem 3.3]). Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$. If c is smooth with $c_d \partial_d H(c) \neq 0$ and critical for α , then for all $l, m < d$ with $l \neq m$ we have

$$\begin{aligned} \tilde{g}''(0)_{lm} &= \frac{c_l c_m}{c_d^2 (\partial_d H)^2} \\ &\quad \times \left(\partial_m H \partial_l H + c_d (\partial_d H \partial_m \partial_l H - \partial_m H \partial_d \partial_l H - \partial_l H \partial_m \partial_d H + \frac{\partial_l H \partial_m H}{\partial_d H} \partial_d^2 H) \right) \Big|_{x=c} \\ \tilde{g}''(0)_{ll} &= \frac{c_l \partial_l H}{c_d \partial_d H} + \frac{c_l^2}{c_d^2 (\partial_d H)^2} \left((\partial_l H)^2 + c_d (\partial_d H \partial_l^2 H - 2 \partial_l H \partial_d \partial_l H + \frac{(\partial_l H)^2}{\partial_d H} \partial_d^2 H) \right) \Big|_{x=c}. \end{aligned}$$

□

In the presence of symmetry Proposition 4.1 simplifies greatly.

Proposition 4.2 ([RWa, Proposition 3.4]). Let $\alpha \in \mathbb{N}_+^d$ and $c \in \mathcal{V}$. If $x \mapsto H(x)$ is symmetric, α has all of its components equal, and c lies in the positive orthant, is strictly minimal, smooth with $c_d \partial_d H(c) \neq 0$, and critical for α , then c has all of its components equal and for all $l, m < d$ with $l \neq m$,

$$\tilde{g}''(0)_{lm} = q, \quad \tilde{g}''(0)_{ll} = 2q, \quad \text{and} \quad \det \tilde{g}''(0) = dq^{d-1},$$

where $q = 1 + \frac{c_l}{\partial_d H} (\partial_d^2 H - \partial_l \partial_d H) \Big|_{x=c}$. □

Proposition 4.3. If $c \in \mathcal{V}$ is smooth with $c_d \partial_d H(c)$, then for all $j < p$ and $w \in W$ we have

$$u_j(w) = (-h(w))^{-p+j} \lim_{y \rightarrow h(w)} \frac{\partial^j}{\partial y^j} \frac{G(w, y)}{Q(w, y)^p},$$

where $Q : ((W \times \mathbb{C}) \cap \mathcal{D}) \setminus \mathcal{V} \rightarrow \mathbb{C}$ is given by $Q(w, y) = \frac{H(w, y)}{y - h(w)}$. Moreover,

$$\lim_{y \rightarrow h(w)} \partial_d^j Q(w, y) = \frac{1}{k+1} \partial_d^{j+1} H(w, h(w)).$$

In particular,

$$u_0(w) = \frac{G(x)}{\left(-h(w) \partial_d H(w, h(w)) \right)^p}.$$

Proof. The first statement is just the definition of u_j .

Let $(w, y) \in ((W \times \mathbb{C}) \cap \mathcal{D}) \setminus \mathcal{V}$. Then $H(w, h(w)) = 0$ and

$$\begin{aligned} Q(w, y) &= \frac{H(w, y)}{y - h(w)} \\ &= \frac{H(w, y)}{y - h(w)} \sum_{n=1}^{\infty} \frac{\partial_d^n H(w, h(w))}{n!} (y - h(w))^n \\ &= \sum_{n=0}^{\infty} \frac{\partial_d^{n+1} H(w, h(w))}{(n+1)!} (y - h(w))^n. \end{aligned}$$

Therefore Q extends to a holomorphic function on $(W \times \mathbb{C}) \cap \mathcal{D}$ and

$$\begin{aligned} \lim_{y \rightarrow h(w)} \partial_d^j Q(w, y) &= \lim_{y \rightarrow h(w)} \sum_{n \geq j} n(n-1) \cdots (n-j+1) \frac{\partial_d^{n+1} H(w, h(w))}{(n+1)!} (y - h(w))^{n-j} \\ &= \frac{1}{j+1} \partial_d^{j+1} H(w, h(w)). \end{aligned}$$

□

5. EXAMPLES

Let us apply the results of Section 3 and 4 to several combinatorial examples. We used Maple 11 to do the calculations, and our worksheets are available at <http://www.cs.auckland.ac.nz/~raichev/research.html>.

First we mention two shortcuts to finding strictly minimal points.

Proposition 5.1 ([PW, Theorem 3.16]). If the coefficients of F are all nonnegative and there is a critical point for α , then there is a minimal critical point for α in \mathbb{R}_+^d . □

A d -variate power series $\sum a_\alpha x^\alpha$ is called **aperiodic** if the \mathbb{Z} -span of $\{\alpha \in \mathbb{N}^d : a_\alpha \neq 0\}$ equals \mathbb{Z}^d .

Proposition 5.2 ([PW, Proposition 3.17]). If $1 - H$ is aperiodic and has nonnegative coefficients, then every minimal point of \mathcal{V} is strictly minimal and lies in \mathbb{R}_+^d . □

Example 5.3 ($d = 2$, $p = 1$, $N = 2$). Consider the bivariate generating function

$$F(x_1, x_2) = \frac{1}{1 - x_1 - x_2 - x_1 x_2}$$

whose coefficients F_{β_1, β_2} are called Delannoy numbers and count the number of lattice paths from $(0, 0)$ to (β_1, β_2) with allowable steps $(1, 0)$, $(0, 1)$ and $(1, 1)$. We compute the first two terms of the asymptotic expansion of $F_{n\alpha}$ as $n \rightarrow \infty$ for $\alpha = (3, 2)$.

The critical points of \mathcal{V} are

$$\left(-\frac{2}{3} + \frac{1}{3}\sqrt{13}, -\frac{3}{2} + \frac{1}{2}\sqrt{13}\right) \quad \text{and} \quad \left(-\frac{2}{3} - \frac{1}{3}\sqrt{13}, -\frac{3}{2} - \frac{1}{2}\sqrt{13}\right).$$

Both points are smooth and the first point, which we denote by c , is strictly minimal by Propositions 5.2 and 5.1.

Applying the results of Sections 3 and 4, we get

$$F_{n\alpha} = (c_1^{-3} c_2^{-2})^n (b_0 n^{-1/2} + b_1 n^{-3/2} + O(n^{-5/2}))$$

as $n \rightarrow \infty$, where $c_1^{-3} c_2^{-2} \approx 71.16220050$, $b_0 = \frac{13^{3/4} \sqrt{3}}{156\sqrt{\pi}} (5 + \sqrt{13}) \approx 0.3690602772$ and $b_1 = -\frac{5 \cdot 13^{3/4} \sqrt{3}}{1898208\sqrt{\pi}} (79\sqrt{13} + 767) \approx -0.01853610557$.

Comparing this approximation with the actual values of $F_{n\alpha}$ for small n (using 10-digit floating-point arithmetic), we get the following table.

n	1	2	4	8	16
$F_{n\alpha}$	25	1289	$4.673345 \cdot 10^6$	$8.527550909 \cdot 10^{13}$	$3.978000114 \cdot 10^{28}$
$c^{-n\alpha}(b_0 n^{-1/2})$	26.26314145	1321.542224	$4.732218447 \cdot 10^6$	$8.581184952 \cdot 10^{13}$	$3.990499094 \cdot 10^{28}$
$c^{-n\alpha}(b_0 n^{-1/2} + b_1 n^{-3/2})$	24.94407138	1288.354900	$4.672799360 \cdot 10^6$	$8.527311037 \cdot 10^{13}$	$3.977972633 \cdot 10^{28}$
one-term relative error	-0.05052565800	-0.02524610085	-0.01259771042	-0.006289501355	-0.003142026054
two-term relative error	0.002237144800	0.0005004654771	0.0001167557713	0.00002812906104	0.000006908245151

For an arbitrary α , the two-term asymptotic expansion of $F_{n\alpha}$ is just as easy to compute symbolically in α . The corresponding constants c_1, c_2, a_1, a_2 are square roots of rational functions of α_1, α_2 , and $\sqrt{\alpha_1^2 + \alpha_2^2}$. The exact formulas are somewhat long, so we omit them.

Example 5.4 ($d = 2, p = 1, N = 5$). Fix $q \in (0, 1)$ and consider the bivariate generating function

$$F(x_1, x_2) = \frac{1 - qx_1}{1 - qx_1 + qx_1x_2 - x_1^2x_2}$$

which arises in the context of quantum random walks. Motivated by an example from [BP], we compute the asymptotics of $F_{n\alpha}$ as $n \rightarrow \infty$ for $\alpha = (2, 1 - q)$.

There is one critical point of \mathcal{V} for α , namely, $c := (1, 1)$. This point is smooth. Explicitly solving for x_2 as a function of x_1 in $H(x_1, x_2) = 0$ and applying the minimum modulus theorem shows that c is minimal. However, c is not finitely minimal, because for every $p_1 \in C(1)$ there exists $p_2 \in C(1)$ such that $(p_1, p_2) \in \mathcal{V}$. By a modification of Lemma 3.5 described in [BP, Theorem 3.2] we may still apply Theorem 3.3 to c . Doing so, we get

$$F_{n\alpha} = b_0 n^{-1/3} + b_4 n^{-5/3} + O(n^{-2})$$

as $n \rightarrow \infty$, where $b_0 = \frac{(1-q)^{2/3}}{3^{2/3}q^{1/3}(1+q)^{1/3}\Gamma(2/3)}$ and $b_4 = -\frac{3^{1/6}(q^4+22q^2+1)\Gamma(2/3)}{280q^{5/3}(q+1)^{5/3}(1-q)^{2/3}\pi}$. The $n^{-2/3}$, n^{-1} , and $n^{-4/3}$ terms are zero.

Comparing this approximation with the actual values of $F_{n\alpha}$ for small n (using 10-digit floating-point arithmetic), we get the following table for $q = 1/2$.

n	2	4	8	16	32
$F_{n\alpha}$	0.1875000000	0.1523437500	0.1221771240	0.09739671811	0.07744253816
$b_0 n^{-1/3}$	0.1953794677	0.1550727862	0.1230813520	0.09768973380	0.07753639314
$b_0 n^{-1/3} + b_4 n^{-5/3}$	0.1855814246	0.1519865960	0.1221092630	0.09738354495	0.07743994970
one-term relative error	-0.04202382773	-0.01791367352	-0.007400959937	-0.003008476011	-0.001211930578
two-term relative error	0.01023240213	0.002344395487	0.0005554313097	0.0001352526066	0.00003342426606

Example 5.5 ($d = 3, p \leq 3, N = 2$). Consider the $(d + 1)$ -variate generating function

$$W(x_1, \dots, x_d, y) = \frac{A(x)}{1 - yB(x)},$$

where $A(x) = 1/(1 - \sum_{j=1}^d \frac{x_j}{x_{j+1}})$, $B(x) = 1 - (1 - e_1(x))A(x)$, and $e_1(x) = \sum_{i=j}^d x_j$. Using the symbolic method (as presented in [FS, Chapter 1], say) it is not difficult to show that W counts all words over a d -ary alphabet Λ , where x_j marks occurrences of letter j of Λ and y marks occurrences of *snaps*, non-overlapping pairs of duplicate letters counted from left to right. Here $A(x)$ counts *snappless* words over Λ , the so-called Smirnov words. For more details see [RWb].

The coefficient $W_{(n,\dots,n,s)}$ is then the number of words with n occurrences of each letter and s snaps. For $n \in \mathbb{N}_+$ let ψ_n be the random variable taking a word over Λ with n occurrences of each letter and returning the number of snaps in the word. We compute the expectation and variance of ψ_n as $n \rightarrow \infty$. If $\alpha = (1, \dots, 1)$, then

$$\begin{aligned}\mathbb{E}(\psi_n) &= \frac{\left(\frac{\partial W}{\partial y}(x, 1)\right)_{n\alpha}}{\left(W(x, 1)\right)_{n\alpha}} = \frac{\left(A(x)^{-1}B(x)(1 - e_1(x))^{-2}\right)_{n\alpha}}{\left((1 - e_1(x))^{-1}\right)_{n\alpha}} \\ \mathbb{E}(\psi_n^2) &= \frac{\left(\frac{\partial^2 W}{\partial y^2}(x, 1) + \frac{\partial W}{\partial y}(x, 1)\right)_{n\alpha}}{\left(W(x, 1)\right)_{n\alpha}} \\ &= \frac{\left(A(x)^{-2}B(x)(B(x) + 1)(1 - e_1(x))^{-3}\right)_{n\alpha}}{\left((1 - e_1(x))^{-1}\right)_{n\alpha}} \\ \mathbb{V}(\psi_n) &= \mathbb{E}(\psi_n^2) - \mathbb{E}(\psi_n)^2.\end{aligned}$$

Let $H(x) = 1 - e_1(x)$. Then the only critical point of \mathcal{V} is $c := (1/d, \dots, 1/d)$, and it is strictly minimal by Propositions 5.1 and 5.2. Applying the results of Sections 3 and 4 to $F_1(x) := W(x, 1)$ (with $p = 1$), $F_2(x) := \partial W / \partial y(x, 1)$ (with $p = 2$), and $F_3(x) := \partial^2 W / \partial y^2(x, 1) + \partial W / \partial y(x, 1)$ (with $p = 3$) with $d = 3$, we obtain

$$\begin{aligned}\mathbb{E}(\psi_n) &= \frac{[(2\pi n)^2 d]^{-1/2} \sum_{j < 2} \sum_{k < 2} \frac{(n+1)^{\overline{1-j}}}{(1-j)! j!} n^{-k} L_k(\tilde{u}_{2,j}, \tilde{g}) + O(n^{-2})}{[(2\pi n)^2 d]^{-1/2} \sum_{j < 1} \sum_{k < 2} \frac{(n+1)^{\overline{-j}}}{(-j)! j!} n^{-k} L_k(\tilde{u}_{2,j}, \tilde{g}) + O(n^{-3})} \\ &= \frac{\frac{3\sqrt{3}}{8\pi} - \frac{61\sqrt{3}}{192\pi} n^{-1} + O(n^{-2})}{\frac{\sqrt{3}}{2\pi} n^{-1} - \frac{\sqrt{3}}{9\pi} n^{-2} + O(n^{-3})} \\ &= \frac{3}{4}n - \frac{15}{32} + O(n^{-1}), \\ \mathbb{E}(\psi_n^2) &= \frac{[(2\pi n)^2 d]^{-1/2} \sum_{j < 3} \sum_{k < 2} \frac{(n+1)^{\overline{2-j}}}{(2-j)! j!} n^{-k} L_k(\tilde{u}_{3,j}, \tilde{g}) + O(n^{-1})}{[(2\pi n)^2 d]^{-1/2} \sum_{j < 1} \sum_{k < 2} \frac{(n+1)^{\overline{-j}}}{(-j)! j!} n^{-k} L_k(\tilde{u}_{1,j}, \tilde{g}) + O(n^{-3})} \\ &= \frac{\frac{9\sqrt{3}}{32\pi} n - \frac{35\sqrt{3}}{128\pi} + O(n^{-1})}{\frac{\sqrt{3}}{2\pi} n^{-1} - \frac{\sqrt{3}}{9\pi} n^{-2} + O(n^{-3})} \\ &= \frac{9}{16}n^2 - \frac{27}{64}n + O(1), \quad \text{and} \\ \mathbb{V}(\psi_n) &= \frac{9}{32}n + O(1).\end{aligned}$$

Comparing these approximations with the actual values for small n (using 10-digit floating-point arithmetic), we get the following table.

n	2	4	8
$\mathbb{E}(\psi_n)$	1.000000000	2.509090909	5.520560294
$(3/4)n$	1.500000000	3	6

6. ASYMPTOTICS OF FOURIER-LAPLACE INTEGRALS

We conclude with the main analytic results behind the proofs of Theorems 3.2 and 3.3. Pemantle and Wilson's approach in [PW02] and our approach here to deriving asymptotics for the Maclaurin coefficients of F requires an asymptotic expansion for integrals of the form

$$\int_X u(t) e^{-\omega g(t)} dt$$

as $\omega \rightarrow \infty$, where $X \subseteq \mathbb{R}^{d-1}$ is open and u and g are complex valued functions on X . Pemantle and Wilson used Watson's lemma and Morse's lemma to prove the existence of a full asymptotic expansion for these Fourier-Laplace integrals as they are commonly called but gave an explicit formula for the leading term only. In contrast we use the two theorems below which give explicit formulas for all terms.

All function spaces mentioned are complex valued.

The first theorem deals with stationary and nondegenerate points, that is, points t_0 such that $g'(t_0) = 0$ and $\det(g''(t_0)) \neq 0$, respectively.

Theorem 6.1 ([Hör83, Theorem 7.7.5]). Let $X \subset \mathbb{R}^{d-1}$ be open, $u \in C_c^\infty(X)$, and $g \in C^\infty(X)$. If $\Re g \geq 0$, $\Re g(t_0) = 0$, g has a unique stationary point $t_0 \in \text{supp } u$, and t_0 is nondegenerate, then for every $N \in \mathbb{N}_+$ there exist $M > 0$ such that

$$\int_X u(t) e^{-\omega g(t)} dt = e^{-\omega g(t_0)} \left(\det \left(\frac{\omega g''(t_0)}{2\pi} \right) \right)^{-1/2} \sum_{k < N} \omega^{-k} L_k(u, g) + O(\omega^{-(d-1)/2-N})$$

for $\omega > 0$. Here L_k is the function defined in Theorem 3.2 (but without the stipulation $t_0 = 0$). Moreover, the big-oh constant is bounded when the partial derivatives of g up to order $3(N + \lceil (d-1)/2 \rceil) + 1$ all stay bounded in supremum norm over X . \square

The second theorem deals with degenerate stationary points for $d = 2$ and is proved by adapting Hörmander's approach.

Theorem 6.2 ([Els, Theorem 1]). Let $X \subset \mathbb{R}$ be open, $u \in C_c^\infty(X)$, and $g \in C^\infty(X)$. If $\Re g \geq 0$, $\Re g(t_0) = 0$, g has a unique stationary point $t_0 \in \text{supp } u$, and $v \geq 2$ is least such that $\tilde{g}^{(v)}(t_0) \neq 0$, then for every $N \in \mathbb{N}_+$ there exists $M > 0$ such that

$$\int_X u(t) e^{-\omega g(t)} dt = e^{-\omega g(t_0)} \frac{2(a\omega)^{-1/v}}{v} \sum_{k < N} \omega^{-2k/v} L_k^{\text{even}}(u, g) + O(\omega^{-(2N+1)/v})$$

for $\omega > 0$ and v even, and

$$\int_X u(t)e^{-\omega g(t)} dt = e^{-\omega g(t_0)} \frac{(|a|(\omega))^{-1/v}}{v} \sum_{k < N} \omega^{-k/v} L_k^{\text{odd}}(u, g) + O(\omega^{-(N+1)/v})$$

for $\omega > 0$ and v odd. Here L_k^{even} and L_k^{odd} are the functions defined in Theorem 3.3 (but without the stipulation $t_0 = 0$). Moreover, the big-oh constants are bounded when the derivatives of g up to order $(v + 1)(N + 1) + 1$ all stay bounded in supremum norm over X . \square

ACKNOWLEDGMENTS

We thank A. F. M. ter Elst for kindly proving Theorem 6.2 on request and proofreading this article.
