

# HIGHER RANDOMNESS NOTIONS AND THEIR LOWNESS PROPERTIES

C. T. CHONG, ANDRE NIES, AND LIANG YU

**ABSTRACT.** We study randomness notions given by higher recursion theory, establishing the relationships  $\Pi_1^1$ -randomness  $\subset$   $\Pi_1^1$ -Martin-Löf randomness  $\subset$   $\Delta_1^1$ -randomness =  $\Delta_1^1$ -Martin-Löf randomness. We characterize the set of reals that are low for  $\Delta_1^1$  randomness as precisely those that are  $\Delta_1^1$ -traceable. We prove that there is a perfect set of such reals.

## 1. INTRODUCTION

In recent years the study of algorithmic randomness has been focused almost exclusively on the arithmetical hierarchy, and with considerable success. In particular,  $n$ -randomness and weak  $n$ -randomness were investigated for  $n < \omega$ . (Recall here that a real in  $2^\omega$  is  $n$ -random if it is not in the intersection of any nested uniformly  $\Sigma_n^0$  sequence  $(V_n)_{n \in \omega}$  of sets of reals so that  $\mu(V_n) \leq 2^{-n}$ . A real is weakly  $n$ -random if it is not in any  $\Pi_n^0$  null set of reals.) Nevertheless, the conceptualization of algorithmic randomness may be approached from a different direction. If one accepts the view that a real is random if it does not satisfy any “reasonable” collection of properties of measure zero, then it makes sense to study randomness relative to a naturally defined notion, and investigate the mathematical properties of reals that are random in the given context. There are two ways of doing this: The first is to study algorithmic  $n$ -randomness by varying the notion of the underlying measure (recent work of Reimann and Slaman, to appear, points to a significant link between being  $n$ -random and the measure that determines randomness), while the second is to retain the classical notion of Lebesgue measure and raise the logical complexity of the sets of reals being considered in the investigation of randomness. In this paper we adopt the second approach and consider randomness within the realm of second order arithmetic. In the spirit of higher recursion theory, we call this the theory of higher randomness.

From the point of view of higher recursion theory, a natural extension of the notion of recursive enumerability for subsets of  $\omega$  in second order arithmetic is  $\Pi_1^1$  definability. An extensive theory has been developed by Kleene, Spector, Gandy, Sacks and others (cf. Sacks [18] for a thorough treatment of the subject). Martin-Löf [11] was the first to study randomness in the setting of higher recursion theory, when he showed that

the intersection of a sequence of hyperarithmetical sets of reals of measure one forms a nonempty  $\Sigma_1^1$  set. For almost 40 years this remained the only contribution to the subject of higher randomness, with the marginal exception of Sacks [18] (Chapter IV, Exercise 2.5). He defined what we call in this paper  $\Pi_1^1$  and  $\Delta_1^1$  random reals, namely those reals avoiding  $\Pi_1^1$  and  $\Delta_1^1$  null sets, respectively. The recent work of Hjorth and Nies [5] may be regarded as the first systematic study of randomness via effective descriptive set theory. In this paper we follow the same direction, by examining various notions we consider to be central to any reasonable theory of randomness. We study them in the setting of higher recursion theory. The motivation is to understand how the choice of a mathematical definability setting determines the key properties of random reals within the structure. We first investigate the analogs of various naturally defined, competing and inequivalent notions of randomness in first order theory. We show that under some circumstances, their analogs are equivalent in second order arithmetic. For instance, a real  $x$  is  $\Delta_1^1$  random if and only if it is  $\Delta_1^1$  random in the sense of Martin-Löf tests. In the case when  $\omega_1^x = \omega_1^{\text{CK}}$ , the equivalence extends to  $x$  being  $\Pi_1^1$  random and being  $\Pi_1^1$  random in the sense of Martin-Löf (Theorem 3.3 and Corollary 3.5; see §3 for the definitions). In general, however, the last two notions do not coincide (Theorem 3.12). In §4 we study an analog of the notion of a real of hyperimmune-free degree, being  $\Delta_1^1$  dominated. We show that the set of  $\Delta_1^1$ -dominated reals has measure 1, and that every  $\Pi_1^1$ -random real is  $\Delta_1^1$ -dominated (Theorem 4.2 and Corollary 4.3). In §5 we study the class of  $\Delta_1^1$  and  $\Pi_1^1$ -traceable sets as analogs of recursive and r.e. traceable reals. It turns out that these two classes are identical, of size the continuum (Theorem 5.4), and properly contained in the class of  $\Delta_1^1$  dominated reals. This is used to study the class of low for  $\Delta_1^1$  random reals where it is proved in §6 Theorem 6.2 that a real is low for  $\Delta_1^1$  random if and only if it is  $\Delta_1^1$ -traceable. We end the paper with further comments on higher randomness, one result on low for  $\Pi_1^1$ -randomness, and some open problems.

## 2. PRELIMINARIES

We assume that the reader is familiar with elements of higher recursion theory, as presented, for instance, in Sacks [18]. Fix a standard  $\Pi_2^0$  set  $H \subseteq \omega \times 2^\omega \times 2^\omega$  so that for all  $x$  and  $n \in \mathcal{O}$ , there is a unique real  $y$  satisfying  $H(n, x, y)$ . Moreover, if  $\omega_1^x = \omega_1^{\text{CK}}$ , then each real  $z \leq_h x$  is Turing reducible to some  $y$  so that  $H(n, x, y)$  holds for some  $n \in \mathcal{O}$ . Roughly speaking,  $y$  is the  $|n|$ -th Turing jump of  $x$ . These  $y$ 's are called  $H^x$  sets and denoted by  $H_n^x$ 's.

We use the Cantor pairing function, the bijection  $p : \omega^2 \rightarrow \omega$  given by  $p(n, s) = \frac{(n+s)^2 + 3n+s}{2}$ , and write  $\langle n, s \rangle = p(n, s)$ .

The following results will be used in later sections.

**Theorem 2.1** (Gandy). *If  $A \subset 2^\omega$  is a nonempty  $\Sigma_1^1$  set, then there is a real  $x \in A$  so that  $\mathcal{O}^x \leq_h \mathcal{O}$ .*

**Theorem 2.2** (Spector [19] and Gandy [4]). *A  $\subset 2^\omega$  is  $\Pi_1^1$  if and only if there is an arithmetical predicate  $P(x, y)$  such that*

$$y \in A \leftrightarrow \exists x \leq_h y P(x, y).$$

**Theorem 2.3** (Sacks[17]). *If  $x$  is non-hyperarithmetical, then  $\mu(\{y|y \geq_h x\}) = 0$ .*

**Theorem 2.4** (Sacks [18]). *The set  $\{x|x \geq_h \mathcal{O}\}$  is  $\Pi_1^1$ . Moreover,  $x \geq_h \mathcal{O}$  if and only if  $\omega_1^x > \omega_1^{\text{CK}}$ .*

A consequence of the last two theorems above is that the set  $\{x|\omega_1^x > \omega_1^{\text{CK}}\}$  is a  $\Pi_1^1$  null set.

The ramified analytical hierarchy was introduced by Kleene, and applied by Feferman [2] and Cohen [1] to study forcing, a tool that turns out to be powerful in the investigation of higher randomness theory. We recall some basic facts here following Sacks [18] whose notations we mostly follow, as given below:

The ramified analytic hierarchy language  $\mathfrak{L}(\omega_1^{\text{CK}}, \dot{x})$  contains the following symbols:

- (1) Number variables:  $j, k, m, n, \dots$ ;
- (2) Numerals:  $0, 1, 2, \dots$ ;
- (3) Constant:  $\dot{x}$ ;
- (4) Ranked set variables:  $x^\alpha, y^\alpha, \dots$  where  $\alpha < \omega_1^{\text{CK}}$ ;
- (5) Unranked set variables:  $x, y, \dots$ ;
- (6) Others symbols include:  $+, \cdot$  (times),  $'$  (successor) and  $\in$ .

Formulas are built in the usual way. A formula  $\varphi$  is *ranked* if all of its set variables are ranked. Due to its complexity, the language is not codable in a recursive set but rather in the countable admissible set  $L_{\omega_1^{\text{CK}}}$ .

To code the language in a uniform way, we fix a  $\Pi_1^1$  path  $\mathcal{O}_1$  through  $\mathcal{O}$  (by [3] such a path exists). Then a ranked set variable  $x^\alpha$  is coded by the number  $(2, n)$  where  $n \in \mathcal{O}_1$  and  $|n| = \alpha$ . Other symbols and formulas are coded recursively. With such a coding, the set of Gödel number of formulas is  $\Pi_1^1$ . Moreover, the set of Gödel numbers of ranked formulas of rank less than  $\alpha$  is r.e. uniformly in the unique notation for  $\alpha$  in  $\mathcal{O}_1$ . Hence there is a recursive function  $f$  so that  $W_{f(n)}$  is the set of Gödel numbers of the ranked formula of rank less than  $|n|$  when  $n \in \mathcal{O}_1$  ( $\{W_e\}_e$  is, as usual, an effective enumeration of r.e. sets).

One now defines a structure  $\mathfrak{A}(\omega_1^{\text{CK}}, x)$ , where  $x$  is a real, analogous to the way Gödel's  $L$  is defined, by induction on the recursive ordinals. Only at successor stages are new sets defined in the structure. The reals constructed at a successor stage are arithmetically definable by the reals constructed at earlier stages. The details may be found in [18]. We define  $\mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi$  for a formula  $\varphi$  of  $\mathfrak{L}(\omega_1^{\text{CK}}, \dot{x})$  by allowing the unranked set variables to range over  $\mathfrak{A}(\omega_1^{\text{CK}}, x)$ , while the symbol  $x^\alpha$  will be interpreted as the reals built before stage  $\alpha$ . In fact, the domain of  $\mathfrak{A}(\omega_1^{\text{CK}}, x)$  is the set  $\{y|y \leq_h x\}$  if and only if  $\omega_1^x = \omega_1^{\text{CK}}$  (see [18]).

A sentence  $\varphi$  of  $\mathfrak{L}(\omega_1^{\text{CK}}, \dot{x})$  is said to be  $\Sigma_1^1$  if it is ranked, or of the form  $\exists x_1, \dots, \exists x_n \psi$  for some formula  $\psi$  with no unranked set variables bounded by a quantifier.

We have the following result which is a model-theoretic version of the Gandy-Spector Theorem.

**Theorem 2.5** (Sacks [18]). *The set  $\{(n_\varphi, x) \mid \varphi \in \Sigma_1^1 \wedge \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi\}$  is  $\Pi_1^1$ , where  $n_\varphi$  is the Gödel number of  $\varphi$ . Moreover, for each  $\Pi_1^1$  set  $A \subseteq 2^\omega$ , there is a formula  $\varphi \in \Sigma_1^1$  so that*

- (1)  $\mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi \implies x \in A$ ;
- (2) if  $\omega_1^x = \omega_1^{\text{CK}}$ , then  $x \in A \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi$ .

Note that if  $\varphi$  is ranked, then both the sets  $\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi\}$  (the Gödel number of  $\varphi$  is omitted) and  $\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \neg\varphi\}$  are  $\Pi_1^1$  and so  $\Delta_1^1$ . Moreover, if  $A \subseteq 2^\omega$  is  $\Delta_1^1$ , then there is a ranked formula  $\varphi$  so that  $x \in A \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi$  (see Sacks [18]).

**Theorem 2.6** (Sacks [17]). *The set  $\{(n_\varphi, p) \mid \mu(\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi\}) > p \wedge \varphi \in \Sigma_1^1 \wedge p \text{ is a rational number}\}$  is  $\Pi_1^1$  where  $n_\varphi$  is the Gödel number of  $\varphi$ .*

**Theorem 2.7** (Sacks [17]). *There is a recursive function  $f : \omega \times \mathbb{Q} \rightarrow \omega$  so that for all  $n$  which is Gödel number of a ranked formula*

- (1)  $f(n, p)$  is Gödel number of a ranked formula;
- (2) The set  $\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi_{f(n, p)}\} \supseteq \{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi_n\}$  is open;
- (3)  $\mu(\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi_{f(n, p)}\}) - \mu(\{x \mid \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi_n\}) < p$ .

**Theorem 2.8** (Sacks [17] and Tanaka [21]). *If  $A$  is a  $\Pi_1^1$  set of positive measure, then  $A$  contains a hyperarithmetical real.*

### 3. DEFINING HIGHER RANDOMNESS NOTIONS

A sequence of open sets  $\{U_n\}_{n \in \omega}$  is a Martin-Löf test (ML-test) if  $\mu(U_n) \leq 2^{-n}$  for all  $n$ . Given a class of sets of reals  $\Gamma$  (e.g.  $\Pi_1^1$  or  $\Delta_1^1$ ),  $\{U_n\}_{n \in \omega}$  is a  $\Gamma$ -ML test if  $\{(n, \sigma) \mid \sigma \in 2^{<\omega} \wedge [\sigma] \in U_n\} \in \Gamma$ .

**Definition 3.1.** *Given a class  $\Gamma$  of sets of reals,*

- (1) *A real  $x$  is  $\Gamma$ -random if no  $\Gamma$  null set contains  $x$ .*
- (2) *A real  $x$  is  $\Gamma$ -ML-random if  $x \notin \bigcap_{n \in \omega} U_n$  for any  $\Gamma$  ML-test  $\{U_n\}_n$ .*

In this paper, we focus on  $\Delta_1^1$ -ML,  $\Delta_1^1$ -,  $\Pi_1^1$ -ML and  $\Pi_1^1$ -randomness. First we show that  $\Delta_1^1$ -randomness and  $\Delta_1^1$ -ML-randomness coincide. For this we need a lemma which will also be used later on. In effect it says that at the hyperarithmetical level, the analogs of computable randomness and Schnorr randomness are the same.

**Lemma 3.2.** *Let  $\mathcal{A}$  be a null  $\Delta_1^1$  set. Then  $\mathcal{A} \subseteq \bigcap U_n$  for some  $\Delta_1^1$ -ML test  $\{U_n\}_{n \in \omega}$  such that, in addition,  $\mu(U_n) = 2^{-n}$  for each  $n$ .*

*Proof.* If  $\mathcal{A}$  is a  $\Delta_1^1$ -null set, then by Theorem 2.7 there is a recursive sequence of  $\Delta_1^1$  open sets  $U_n$  for which  $\mu(U_n) < 2^{-n}$  and  $\mathcal{A} \subseteq U_n$  for all  $n$ . So  $\{U_n\}_{n \in \omega}$  is a  $\Delta_1^1$ -ML-test.

It now suffices to show that the  $\Delta_1^1$ -ML test  $\{U_n\}_{n \in \omega}$  can be improved to a  $\Delta_1^1$ -ML test  $\{\hat{U}_n\}_{n \in \omega}$  such that  $U_n \subseteq \hat{U}_n$  and  $\mu(\hat{U}_n) = 2^{-n}$  for each  $n$ . For this, it clearly suffices to show that for each  $\Delta_1^1$  open set  $S \subseteq 2^\omega$  and each rational  $q \geq \mu(S)$  one can effectively obtain a  $\Delta_1^1$  open set  $\hat{S}$  such that  $S \subseteq \hat{S} \subseteq 2^\omega$  and  $\mu(\hat{S}) = q$ . Recall the

isometry  $F$  between the conull subset of Cantor space  $2^\omega$  consisting of the coinfinite sets and the interval  $I = [0, 1]_{\mathbb{R}}$ : for a coinfinite set  $z \subseteq \omega$ , let

$$F(z) = \sum_{i \in z} 2^{-i-1}.$$

Note that under  $F$ , the product measure  $\mu$  turns into Lebesgue measure, and the lexicographical ordering  $<_L$  becomes the usual ordering of real numbers. The function  $f : I \rightarrow I$  given by  $f(x) = \mu([0, x) \cup F(S))$  is continuous, non-decreasing and  $f(0) \leq q$  while  $f(x) \geq x$  for each  $x \in I$ . Thus there is a least  $r$  such that  $f(r) = q$ . Since  $f \in \Delta_1^1$  and the left cut of  $r$  is  $\{s \in \mathbb{Q} | f(s) < q\}$ , the real number  $r$  is  $\Delta_1^1$ , so  $F(z) = r$  for some hyperarithmetical coinfinite  $z \subseteq \omega$ . Now the open set  $\hat{S} = \{y | y <_L z\} \cup S$  is as desired.  $\square$

**Theorem 3.3.** *The following are equivalent for a real  $x$ .*

- (i)  $x$  is  $\Delta_1^1$ -random
- (ii)  $x$  is  $\Delta_1^1$ -ML-random

*Proof.* (i)  $\Rightarrow$  (ii): If  $\{\hat{U}_n\}_{n \in \omega}$  is a  $\Delta_1^1$ -ML-test, then  $V = \bigcap_{n \in \omega} \hat{U}_n$  is a  $\Delta_1^1$  null set. So  $x \notin V$ .

(ii)  $\Rightarrow$  (i): This is an immediate consequence of the previous lemma.  $\square$

Hjorth and Nies [5] gave a direct proof of the result that the union of all  $\Pi_1^1$  null sets is  $\Pi_1^1$ , which may also be obtained as a special case of the more general result [7, Theorem 1A-2]. We give yet another proof via the ramified analytical hierarchy, in order to extract more information about the set.

**Theorem 3.4** (Kechris [7]; Hjorth and Nies [5]). *The largest null  $\Pi_1^1$  set exists.*

*Proof.* Define

$$\mathcal{P} = \{(n, x) | n \text{ is the Gödel number of a ranked formula}$$

$$\wedge \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi_n(\dot{x}) \wedge \mu(\{x | \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \neg \varphi_n(\dot{x})\}) \geq 1\}$$

and

$$\mathcal{Q}_n = \{x | (n, x) \in \mathcal{P}\}.$$

Define

$$\mathcal{Q} = \bigcup_{n \in \omega} \mathcal{Q}_n \cup \{x | \omega_1^x > \omega_1^{\text{CK}}\}.$$

We show that  $\mathcal{Q}$  is the largest null  $\Pi_1^1$  set. By Theorem 2.6, the sequence  $\{\mathcal{Q}_n\}_{n \in \omega}$  is a  $\Pi_1^1$ -sequence of  $\Delta_1^1$  sets.  $\mathcal{Q}$  is  $\Pi_1^1$ . Moreover,  $\mu(\mathcal{Q}_n) = 0$  for all  $n \in \omega$ . Since  $\mu(\{x | \omega_1^{\text{CK}} = \omega_1^x\}) = 1$ ,  $\mu(\mathcal{Q}) = 0$ .

If  $A$  is a  $\Pi_1^1$  null set, then, by Theorem 2.5, there is a ranked formula  $\varphi \in \Sigma_1^1$  so that if  $\omega_1^x = \omega_1^{\text{CK}}$ , then  $x \in A \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \exists y \varphi(\dot{x}, y)$ . So if  $\omega_1^x = \omega_1^{\text{CK}}$ , then  $x \in A \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \exists y^\alpha \varphi(\dot{x}, y^\alpha)$  for some  $\alpha < \omega_1^{\text{CK}}$ . Since the set  $\{x | \omega_1^x > \omega_1^{\text{CK}}\}$  is null, it is easy to see that  $A \subseteq \mathcal{Q}$ .  $\square$

**Corollary 3.5.** *Suppose  $\omega_1^x = \omega_1^{\text{CK}}$ . Then  $x$  is  $\Delta_1^1$ -random if and only if  $x$  is  $\Pi_1^1$ -ML-random, and this is equivalent to  $x$  being  $\Pi_1^1$ -random.*

*Proof.* Clearly  $\Pi_1^1$ -randomness implies  $\Pi_1^1$ -ML-randomness. By Theorem 3.3, it suffices to show that if  $x$  is  $\Delta_1^1$ -random and  $\omega_1^x = \omega_1^{\text{CK}}$ , then  $x$  is  $\Pi_1^1$ -random. Assume  $\omega_1^x = \omega_1^{\text{CK}}$ . If  $x$  is  $\Delta_1^1$ -random, then  $x \notin \mathcal{Q}_n$  for all  $n$ . So  $x \notin \mathcal{Q}$ . Hence  $x$  is  $\Pi_1^1$ -random.  $\square$

In contrast to Theorem 3.4, we have the following.

**Proposition 3.6.** *There is no largest null  $\Sigma_1^1$  set.*

*Proof.* Suppose  $A$  is the largest null  $\Sigma_1^1$  set. Then by the Tanaka-Sacks Theorem 2.8, there is a  $\Delta_1^1$  real  $x \notin A$ .  $X = \{x\}$  is  $\Delta_1^1$  and  $X \cap A = \emptyset$ , a contradiction.  $\square$

By Theorem 2.4 and the proof of Theorem 3.4, we have the following result.

**Proposition 3.7** (Hjorth and Nies [5]). *If  $x$  is  $\Pi_1^1$ -random, then  $\omega_1^x = \omega_1^{\text{CK}}$ .*

Together with Corollary 3.5, the  $\Pi_1^1$ -random reals are precisely the  $\Delta_1^1$ -random reals  $x$  that also satisfy  $\omega_1^x = \omega_1^{\text{CK}}$ .

By the Gandy Basis Theorem 2.1, there is a  $\Pi_1^1$ -random real  $x$  with  $\mathcal{O}^x \leq_h \mathcal{O}$ .

**Theorem 3.8** (Hjorth and Nies [5]). *Given any real  $x$ , there is a  $\Pi_1^1$ -ML-random real  $y \geq_h x$ .*

Combining Theorem 3.8 and Proposition 3.7, we have the following consequence.

**Corollary 3.9** (Hjorth and Nies [5]). *There is a  $\Pi_1^1$ -ML-random real that is not  $\Pi_1^1$ -random.*

We now separate  $\Delta_1^1$ -randomness from  $\Pi_1^1$ -ML-randomness, which is needed for the proof of Theorem 3.12 below. If one views the randomness notions as operators mapping oracles to classes, the separation can be obtained as a consequence of Theorem 5.4, Theorem 6.2, and the result of Hjorth and Nies [5] that every low for  $\Pi_1^1$ -ML-random real is hyperarithmetical. We now obtain the separation for the plain randomness notions. Recall that in [5] a  $\Pi_1^1$  version of prefix free Kolmogorov complexity was introduced, denoted by  $K$ . It was shown that a Theorem analogous to the one of Schnorr holds, namely:  $z$  is  $\Pi_1^1$ -ML-random if and only if there is a  $b \in \omega$  such that for each  $n$ ,  $K(z \upharpoonright n) \geq n - b$ . So the following result implies the separation:

**Theorem 3.10.** *Let  $h$  be a nondecreasing  $\Delta_1^1$  function such that  $\lim_n h(n) = \infty$ . Then there is a  $\Delta_1^1$ -random real  $z$  such that  $\forall^\infty n K(z \upharpoonright n \mid n) \leq h(n)$ .*

Here,  $K(\sigma \mid n)$  is the complexity of  $\sigma$  given  $n$ . A number  $n$  is encoded in some effective way by a string (say the binary expansion). Then  $K(\sigma) \leq K(\sigma \mid n) + 2 \log n$  (up to constants), so if we let  $h(n) = \log n$  then we obtain  $K(z \upharpoonright n) \leq 3 \log n$ .

First we need some preliminaries. A function  $f : 2^{<\omega} \rightarrow \mathbb{R}^+ \cup \{0\}$  is hyperarithmetical if there is a hyperarithmetical approximation function  $g : 2^{<\omega} \times \omega \rightarrow \mathbb{Q}^+ \cup \{0\}$  such that for each  $\sigma$  and  $n$ , we have  $|f(\sigma) - g(\sigma, n)| \leq 2^{-n}$ . A hyperarithmetical

martingale is a hyperarithmetical function  $M : 2^{<\omega} \rightarrow \mathbb{R}^+ \cup \{0\}$  that satisfies for every  $\sigma \in 2^{<\omega}$  the martingale equality  $M(\sigma 0) + M(\sigma 1) = 2M(\sigma)$ . For a martingale  $M$  and a real  $z$ , let  $M(z) = \sup_n M(z \upharpoonright n)$ . We say that the martingale  $M$  succeeds on  $z$  if the capital it reaches along  $z$  is unbounded, that is,  $M(z) = \infty$ . Let  $S(M) = \{z \mid M \text{ succeeds on } z\}$ .

Of course,  $S(M)$  is a  $\Delta_1^1$  null set for any hyperarithmetical martingale  $M$ . Here is the converse. This equivalence is an effectivization of Ville's theorem.

**Lemma 3.11.** *Let  $\mathcal{A}$  be a  $\Delta_1^1$  null set. Then there is a hyperarithmetical martingale  $M_{\mathcal{A}}$  such that  $\mathcal{A} \subseteq S(M_{\mathcal{A}})$ .*

*Proof.* By Lemma 3.2 there is a  $\Delta_1^1$  ML test  $\{U_n\}_{n \in \omega}$  such that  $\mu(U_n) = 2^{-n}$  and  $\mathcal{A} \subseteq U_n$  for all  $n$ . Let  $M_n(\sigma) = \mu(U_n \cap [\sigma])2^{|\sigma|}$ . Then  $M_n$  is a hyperarithmetical martingale, uniformly in  $n$ , and  $M_n(z) = 1$  if  $z \in U_n$ . Moreover, the start capital  $M_n(\emptyset)$  is  $2^{-n}$ . Now let  $M(\sigma) = \sum_n M_n(\sigma)$ , then  $M$  is as required.  $\square$

The proof of Theorem 3.10 is a straightforward computably random reals, see for instance [14, Ch. 7]. We build a real  $z$  of slowly growing initial segment complexity (in the sense above) on which no  $\mathbb{Q}$ -valued hyperarithmetical martingale  $L$  succeeds. The martingale  $M_{\mathcal{A}}$  is not necessarily  $\mathbb{Q}$ -valued, but by adaptation of a standard argument due to Schnorr (ibd.), for each hyperarithmetical martingale  $M$  there is a  $\mathbb{Q}$ -valued hyperarithmetical martingale  $\hat{M}$  such that  $\hat{M}(\sigma) \geq M(\sigma)$  for each  $\sigma$ .

In the following theorem we summarize the implications between the various randomness notions.

**Theorem 3.12.**

$$\begin{aligned} \Delta_1^1(\mathcal{O})\text{-randomness} &\Rightarrow \Pi_1^1\text{-randomness} \\ &\Rightarrow \Pi_1^1\text{-ML-randomness} \\ &\Rightarrow \Delta_1^1\text{-randomness} \\ &\Leftrightarrow \Delta_1^1\text{-ML-randomness}, \end{aligned}$$

and none of the implications may be reversed.

*Proof.*  $\Delta_1^1(\mathcal{O})$ -randomness  $\Rightarrow \Pi_1^1$ -randomness: Fix an  $\mathcal{O}$ -recursive well ordering  $<_R$  on  $\omega$  of order type  $\omega_1^{\text{CK}}$ . Then

$$\begin{aligned} \omega_1^x > \omega_1^{\text{CK}} &\Leftrightarrow \exists S \subseteq \omega \times \omega \exists f \in \omega^\omega \\ S \leq_T x \wedge \forall n \exists m (f(m) = n) \wedge \forall n \forall m (S(n, m) &\iff f(n) <_R f(m))). \end{aligned}$$

So the set  $\{x \mid \omega_1^x > \omega_1^{\text{CK}}\}$  is  $\Sigma_1^1(\mathcal{O})$ . By Theorem 2.4,  $\{x \mid \omega_1^x > \omega_1^{\text{CK}}\}$  is  $\Delta_1^1(\mathcal{O})$ . Note that the sequence  $\{\mathcal{Q}_n\}_{n \in \omega}$  is a  $\Pi_1^1$ -sequence, and so is an  $\mathcal{O}$ -recursive sequence of  $\Delta_1^1(\mathcal{O})$  sets. So  $\mathcal{Q} = \bigcup_{n \in \omega} \mathcal{Q}_n \cup \{x \mid \omega_1^x > \omega_1^{\text{CK}}\}$  is a null  $\Delta_1^1(\mathcal{O})$  set. Hence  $\Delta_1^1(\mathcal{O})$ -randomness  $\Rightarrow \Pi_1^1$ -randomness. By the Gandy Basis Theorem 2.1, there is a  $\Pi_1^1$ -random real  $x \leq_h \mathcal{O}$ . Now  $x$  cannot be  $\Delta_1^1(\mathcal{O})$ -random. Thus the implication cannot be reversed.

$\Pi_1^1$ -randomness  $\Rightarrow \Pi_1^1$ -ML-randomness: It is clear that  $\Pi_1^1$ -randomness  $\subseteq \Pi_1^1$ -ML-randomness. By Theorem 3.8, there exists a  $\Pi_1^1$ -ML-random real  $x \geq_h \mathcal{O}$ .  $x$  cannot be  $\Pi_1^1$ -random.

Obviously  $\Pi_1^1$ -ML-randomness  $\Rightarrow \Delta_1^1$ -randomness. It follows from the Theorem 3.10 that the implication cannot be reversed.

Finally,  $\Delta_1^1$ -randomness  $\Leftrightarrow \Delta_1^1$ -ML-randomness is Theorem 3.3.  $\square$

The reader may wonder why we do not study  $\Sigma_1^1$ -randomness. In fact this is done implicitly—the following proposition says that  $\Sigma_1^1$ -randomness coincides with  $\Delta_1^1$ -randomness.

**Proposition 3.13.** *If  $A$  is  $\Pi_1^1$  and  $\mu(A) = 1$ , then there is a conull  $\Delta_1^1$  set  $B \subseteq A$ .*

*Proof.* Suppose  $A$  is a  $\Pi_1^1$ -set for which  $\mu(A) = 1$ . Then, by Theorem 2.5, there is a ranked formula  $\varphi(\dot{x}, y)$  so that for all  $n \in \mathcal{O}_1$ ,  $A_n \subseteq A$ , where  $A_n = \{x | \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \exists y^{[n]} \varphi(\dot{x}, y^{[n]})\}$ . Since the set  $\{x | \omega_1^x > \omega_1^{\text{CK}}\}$  is null and  $A_n \subseteq A_m$  for all  $n <_o m$  in  $\mathcal{O}_1$ , by Theorem 2.5,  $\mu(A) = \mu(\bigcup_{n \in \mathcal{O}_1} A_n)$ . Define  $R(k, n)$  if and only if  $\mu(A_n) > 1 - 2^{-k}$ . By Theorem 2.6,  $R$  is a  $\Pi_1^1$  relation. By the  $\Pi_1^1$  Uniformitarian Theorem (see [13]), there is a  $\Pi_1^1$  function  $f : \omega \rightarrow \omega$  uniformizing  $R$ . Since  $\mu(A) = 1$ ,  $f$  is a total function. So  $f$  is  $\Delta_1^1$ . Hence the range  $S$  of  $f$  is  $\Delta_1^1$ . Then there must a recursive ordinal  $\alpha$  so that  $|n| < \alpha$  for all  $n \in S$  (otherwise,  $\mathcal{O}_1$  would be  $\Delta_1^1$ ). Fix the notation  $n \in \mathcal{O}_1$  so that  $|n| = \alpha$ . Define  $B = A_n$ . Then  $\mu(B) = 1$  and  $B \subseteq A$ .  $\square$

#### 4. $\Delta_1^1$ -DOMINATED REALS

A real  $x$  is of hyperimmune-free degree if every function Turing reducible to  $x$  is dominated by a recursive function. We study an analog of this notion in the setting of effective descriptive set theory:

**Definition 4.1.** *A real  $x$  is  $\Delta_1^1$ -dominated if for all functions  $f : \omega \rightarrow \omega$  with  $f \leq_h x$ , there is a hyperarithmetic function  $g$  so that  $g(n) > f(n)$  for all  $n$  (written as  $g > f$ ).*

The following contrasts with the result that the reals of hyperimmune-free degree have measure 0 ([10]; see [15] for a short proof).

**Theorem 4.2.**  $\mu(\{x | x \text{ is } \Delta_1^1\text{-dominated}\}) = 1$ .

*Proof.* We prove that for any rational number  $p$ , the measure of

$$\{x | x \text{ is } \Delta_1^1\text{-dominated}\}$$

is not less than  $p$ . We apply a fusion argument to achieve this.

Firstly we show that for any number  $e$ , rational  $r$ , notation  $n \in \mathcal{O}$  and  $\Delta_1^1$  set  $A$  for which  $p + r < \mu(A)$ , there is a hyperarithmetic function  $f$  so that

$$\mu(\{x | x \in A \wedge \Phi_e^{H_n^x}(i) \text{ is total} \implies \Phi_e^{H_n^x}(i) < f\}) > p + \frac{r}{2}.$$

Since the set  $\{(x, i, m) | \Phi_e^{H_n^x}(i) \downarrow \implies \Phi_e^{H_n^x}(i) < m\}$  is  $\Delta_1^1$ , there is a ranked formula  $\varphi(\dot{x}, i, m)$  so that  $\mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi(\dot{x}, i, m)$  if and only if  $\Phi_e^{H_n^x}(i) < m$ . Since  $A$  is  $\Delta_1^1$ , by Theorem 2.6, the set

$$C = \{(i, m, k) | \wedge \mu(\{x | x \in A \wedge (\Phi_e^{H_n^x}(i) \downarrow \implies \Phi_e^{H_n^x}(i) < m)\}) > \mu(A) - \frac{r}{2^{k+2}}\}$$

is  $\Delta_1^1$ . Note that for each  $k$ , there is a number  $m$  so that  $(k, m, k) \in C$ . So there is a  $\Delta_1^1$  total function  $f$  so that for all  $k$ ,  $(k, f(k), k) \in C$ . Define

$$B_k = \{x|x \in A \wedge (\Phi_e^{H_n^x}(k) \downarrow \implies \Phi_e^{H_n^x}(k) < f(k))\}.$$

Then the set  $\{(k, x)|x \in B_k\}$  is  $\Delta_1^1$ . Moreover, for every  $k$ ,  $B_k \subseteq A$  and  $\mu(B_k) > \mu(A) - \frac{r}{2^{k+2}}$ . So the set  $B = \bigcap_k B_k$  is  $\Delta_1^1$  and

$$\mu(B) \geq \mu(A) - \sum_{k \geq 0} \mu(A - B_k) \geq p + r - \sum_{k \geq 0} \frac{r}{2^{k+2}} = p + \frac{r}{2}.$$

Moreover, for every  $x \in B$ , if  $\Phi_e^{H_n^x}$  is total, then  $\Phi_e^{H_n^x} < f$ . Thus we may construct an  $\omega$ -sequence of  $\Delta_1^1$  sets  $\{B^{\langle e, n \rangle}\}_{e \in \omega \wedge n \in \mathcal{O}}$  so that for all  $e \in \omega$  and  $n \in \mathcal{O}$ ,

- (1) If  $\langle e, n \rangle > \langle e', n' \rangle$ , then  $B^{\langle e, n \rangle} \subseteq B^{\langle e', n' \rangle}$ ;
- (2)  $\mu(B^{\langle e, n \rangle}) > p$ .

Define  $D = \bigcap_{e \in \omega \wedge n \in \mathcal{O}} B^{\langle e, n \rangle}$ . Then  $D \subseteq \{x|x \text{ is } \Delta_1^1\text{-dominated}\}$  and  $\mu(D) \geq p$ . Moreover, each real in  $D$  is  $\Delta_1^1$ -dominated.  $\square$

**Corollary 4.3.** *Each  $\Pi_1^1$ -random real is  $\Delta_1^1$ -dominated.*

*Proof.* By the proof of Theorem 4.2, for each  $e \in \omega$  and  $n \in \mathcal{O}$ , the set  $A_{e,n} = \{x|\exists f \in \Delta_1^1(\Phi_e^{H_n^x} \text{ is total} \implies \Phi_e^{H_n^x} < f)\}$  has measure 1. Note that  $A_{e,n}$  is  $\Pi_1^1$ . So, by Proposition 3.13, if  $x$  is  $\Delta_1^1$ -random, then  $x \notin A_{e,n}$ . Now if  $x$  is  $\Pi_1^1$ -random, then, by Proposition 3.7,  $\omega_1^{\text{CK}} = \omega_1^x$ . So if  $g \leq_h x$ , then  $g = \Phi_e^{H_n^x}$  for some  $e, n \in \mathcal{O}$ . Thus each  $\Pi_1^1$ -random is  $\Delta_1^1$ -dominated.  $\square$

Note that  $\Pi_1^1$ -randomness cannot be improved to  $\Delta_1^1$ -randomness in Corollary 4.3 since there exists a  $\Delta_1^1$ -random real  $x \geq_h \mathcal{O}$  (see [5]), and by the following proposition.

**Proposition 4.4.**  $\{x|x \text{ is } \Delta_1^1\text{-dominated}\} \subset \{x|\omega_1^x = \omega_1^{\text{CK}}\}$ .

*Proof.* If  $\omega_1^x > \omega_1^{\text{CK}}$ , then  $x \geq_h \mathcal{O}$ . Since there is an  $\mathcal{O}$ -arithmetical enumeration of  $\Delta_1^1$  functions  $\{f_n\}_{n \in \omega}$ , there is a  $\Delta_1^1(x)$  enumeration. Define  $g(n) = f_n(n) + 1$ . Then  $g \leq_h x$ . So  $x$  is not  $\Delta_1^1$ -dominated. Thus  $\{x|x \text{ is } \Delta_1^1\text{-dominated}\} \subseteq \{x|\omega_1^x = \omega_1^{\text{CK}}\}$ .

To see that the relation is proper, we apply Cohen forcing developed in [18]. The forcing conditions are elements of  $2^{<\omega}$ . A real is said to be generic if each  $\Sigma_1^1$ -sentence or its negation is forced by a finite initial segment of  $x$ . So generic reals form a comeager set. Feferman (see [2] or [18]) proved that  $\mathfrak{A}(\omega_1^{\text{CK}}, x)$  satisfies  $\Delta_1^1$ -comprehension for any generic real  $x$ . So  $\omega_1^x = \omega_1^{\text{CK}}$  (see [18]). We claim that no generic real can be  $\Delta_1^1$ -dominated.

Given a real  $x$ , define  $g_x(n) = m_n$  if  $m_n$  is the  $n$ -th bit of  $x$  so that  $x(m_n) = 1$ . So there is a recursive functional  $\Phi$  such that  $\Phi^x = g_x$  for all  $x$ . Hence there is a ranked (and so  $\Sigma_1^1$ ) formula  $\varphi$  defining  $g_x$ , i.e.  $g_x(n) = m \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \varphi(\dot{x}, n, m)$ . For any  $\Delta_1^1$  function  $f$ , there is a ranked formula  $\psi_f$  defining  $f$ , i.e.  $f(n) = m \Leftrightarrow \mathfrak{A}(\omega_1^{\text{CK}}, x) \models \psi_f(n, m)$ . So if  $\mathfrak{A}(\omega_1^{\text{CK}}, x) \models \forall n(f(n) > g_x(n))$ , then there is a finite string  $p \prec x$  so that  $p \Vdash \forall n(f(n) > g_x(n))$ . This is impossible since one can easily find a condition  $q$  stronger than  $p$  so that  $q \Vdash \exists n(f(n) < g_x(n))$ .

Thus  $\{x|x \text{ is } \Delta_1^1\text{-dominated}\} \subset \{x|\omega_1^x = \omega_1^{\text{CK}}\}$ .  $\square$

One might conjecture that, by analogy to the effective case, the  $\Delta_1^1$ -dominated reals form a basis for  $\Sigma_1^1$  sets. This is, however, false.

**Proposition 4.5.** *There is a nonempty  $\Sigma_1^1$  set  $A \subseteq 2^\omega$  which does not contain any  $\Delta_1^1$ -dominated real.*

*Proof.* As in the proof of Proposition 4.4, there is a recursive functional  $\Phi$  so that the set  $A = \{x \mid \forall f \in \Delta_1^1 (f \not\geq \Phi^x)\}$  is non-empty. By Theorem 2.2 (the Spector-Gandy Theorem),  $A$  is a nonempty  $\Sigma_1^1$  set.  $\square$

## 5. $\Delta_1^1$ -TRACEABLE REALS

Next we consider the notions analogous to being r.e. traceable and recursively traceable in first order randomness theory, both of which are studied in [22, 9] (see for instance [9, Section 2.2] for the formal definition). The corresponding notions are called  $\Pi_1^1$ -traceability and  $\Delta_1^1$ -traceability, respectively. We shall show that they are in fact equivalent.

**Definition 5.1.** (i) Let  $h : \omega \rightarrow \omega$  be a nondecreasing unbounded function that is hyperarithmetical. A  $\Pi_1^1$ -trace/ $\Delta_1^1$ -trace with bound  $h$  is a uniformly  $\Pi_1^1$ /uniformly  $\Delta_1^1$  sequence  $(T_e)_{e \in \omega}$  such that  $|T_e| \leq h(e)$  for each  $e$ .  
(ii)  $A \subseteq \omega$  is  $\Pi_1^1$ -traceable/ $\Delta_1^1$ -traceable if there is  $h \in \Delta_1^1$  such that, for each  $f \leq_h A$ , there is a  $\Pi_1^1$ -trace/ $\Delta_1^1$ -trace with bound  $h$  such that, for each  $e$ ,  $f(e) \in T_e$ .

Note that, if  $(T_e)_{e \in \omega}$  is a uniformly  $\Delta_1^1$  sequence of finite sets, then there is  $g \in \Delta_1^1$  such that for each  $e$ ,  $D_{g(e)} = T_e$  (where  $D_n$  is the  $n$ th finite set according to some recursive ordering). Thus

$$g(e) = \mu n \forall u [u \in D_n \leftrightarrow u \in T_e].$$

In this formulation, the definition of  $\Delta_1^1$  traceability is very close to that of recursive traceability. It is not difficult to see that every  $\Delta_1^1$ -traceable real is  $\Delta_1^1$ -dominated.

Also notice that the choice of a bound as a witness for traceability is immaterial:

**Proposition 5.2** (Terwijn and Zambella [22]). *Let  $A$  be a real that is  $\Delta_1^1$  traceable with bound  $h$ . Then for any monotone and unbounded  $\Delta_1^1$  function  $h'$ ,  $A$  is  $\Delta_1^1$  traceable with bound  $h'$ . The same holds for  $\Pi_1^1$  traceability.*

The class of r.e. traceable sets is strictly larger than the class of recursively traceable sets, since the former contains nonrecursive r.e. sets [9]. In contrast, we have the following equivalence:

**Proposition 5.3.** *If  $x$  is  $\Pi_1^1$ -traceable, then  $x$  is  $\Delta_1^1$ -traceable.*

*Proof.* We first claim that  $\omega_1^x = \omega_1^{\text{CK}}$ . Otherwise  $x \geq_h \mathcal{O}$ . So it is sufficient to show that  $\mathcal{O}$  is not  $\Pi_1^1$ -traceable. Since each  $\Pi_1^1$  set is many-one reducible to  $\mathcal{O}$  [16, 5.4 I], there is a uniformly  $\mathcal{O}$ -recursive list  $(T^e)_{e \in \omega}$  of all  $\Pi_1^1$ -traces for the bound  $h(e) = e$ . Define  $f \leq_h \mathcal{O}$  by

$$f(e) = \mu n [n \notin T^e],$$

then  $f$  does not have a  $\Pi_1^1$  trace.

To complete the proof, given  $f \leq_h x$ , there is a  $\Pi_1^1$  trace  $(T_e)_{e \in \omega}$  such that  $f(e) \in T_e$  for each  $e$ . Then there is a recursive function  $h : \omega^2 \rightarrow \omega$  so that  $k \in T_e$  if and only if  $h(k, e) \in \mathcal{O}$ . Define a  $\Pi_1^1(x)$ -relation  $R \subseteq \omega \times \mathcal{O}$  by

$$(e, n) \in R \Leftrightarrow h(e, f(e)) \in \mathcal{O}_n,$$

where  $\mathcal{O}_n = \{m \in \mathcal{O} \mid |m| < |n|\}$ , a  $\Delta_1^1$  set. Note that for each  $e$ , there is a notation  $n \in \mathcal{O}$  so that  $(e, n) \in R$ . By the Kreisel Uniformization Theorem, there is a total  $\Pi_1^1(x)$  (and so  $\Delta_1^1(x)$ ) function  $g$  uniformizing  $R$ . Hence the range  $S = \{n \mid \exists e[g(e) = n]\}$  of  $g$  is a  $\Delta_1^1(x)$  set. Since  $\omega_1^x = \omega_1^{\text{CK}}$ , there exists a notation  $n_0 \in \mathcal{O}$  so that  $S \subseteq \mathcal{O}_{n_0}$  (otherwise the well-founded relation “ $i <_o j$ ” would be  $\Delta_1^1(x)$ ). Define a set  $\hat{T}_e \subseteq T_e$  as follows:

$$k \in \hat{T}_e \Leftrightarrow h(k, e) \in \mathcal{O}_{n_0}.$$

By the definition of  $n_0$ ,  $f(e) \in \hat{T}_e$  for all  $e \in \omega$ . Note that the relation  $n \in \hat{T}_e$  is  $\Delta_1^1$ . Hence  $(\hat{T}_e)_{e \in \omega}$  is a  $\Delta_1^1$ -trace for  $f$ . So  $f$  is  $\Delta_1^1$ -traceable.  $\square$

**Theorem 5.4.** *There are  $2^{\aleph_0}$ -many  $\Delta_1^1$ -traceable reals.*

*Proof.* We apply Sacks forcing to show this (see [18]). The forcing conditions are perfect trees coded by  $\Delta_1^1$  reals. A real  $x$  is Sacks generic if for each  $\Sigma_1^1$  sentence  $\varphi$ , there is a condition  $T$  so that  $x \in T$  and  $T \Vdash \varphi$  or  $T \Vdash \neg\varphi$ . Sacks proved that the set  $\{(T, n_\varphi) \mid \varphi \in \Sigma_1^1 \wedge T \Vdash \varphi\}$  is  $\Pi_1^1$ . We claim that each Sacks generic real is  $\Delta_1^1$ -traceable. Thus there are  $2^{\aleph_0}$ -many  $\Delta_1^1$ -traceable reals.

Suppose  $x$  is a Sacks generic real. Since  $x$  has minimal hyperdegree (see [18]),  $\omega_1^{\text{CK}} = \omega_1^x$ . So if  $f \leq_h x$ , then there is a number  $e$  and a notation  $n \in \mathcal{O}$  so that  $\Phi_e^{H_n^x} = f$ . Since the set  $A = \{(y, n, i, j) \mid \Phi_e^{H_n^y}(i) = j\}$  is  $\Delta_1^1$ , there exists a ranked formula defining  $A$ . Since  $\Phi_e^{H_n^x}$  is total, by the definition of Sacks genericity, there is a condition  $T \Vdash “\Phi_e^{H_n^x} \text{ is total}”$ . We show that for each condition  $S \subseteq T$ , there is a condition  $Q \subseteq S$  so that  $Q \Vdash “\exists f(f \in \Delta_1^1 \wedge \forall i(\Phi_e^{H_n^x}(i) \in D_{f(i)} \wedge |D_{f(i)}| \leq 2^{i+1}))”$ . Then, by the definition of forcing, there is a  $\Delta_1^1$  function  $f$  so that for all  $i$ ,  $\Phi_e^{H_n^x}(i) \in D_{f(i)} \wedge |D_{f(i)}| \leq 2^{i+1}$ .

Since  $T \Vdash “\Phi_e^{H_n^x} \text{ is total}”$ ,  $S \Vdash “\Phi_e^{H_n^x} \text{ is total}”$ .

Case (1). There is a condition  $R \subseteq S$  so that for all  $i, j_0, j_1$ , for all conditions  $P_0, P_1 \subseteq R$ ,  $P_0 \Vdash \Phi_e^{H_n^x}(i) = j_0$  and  $P_1 \Vdash \Phi_e^{H_n^x}(i) = j_1$  implies  $j_0 = j_1$ . Then we define  $f(i) = j$  if and only if there exists a condition  $P \subseteq R$  so that  $P \Vdash \Phi_e^{H_n^x}(i) = j$ . Then  $f$  is a total  $\Pi_1^1$ -function and hence  $\Delta_1^1$ . This implies that  $R \Vdash f = \Phi_e^{H_n^x}$ .

Case (2). Otherwise. Define a relation  $\mathcal{R}(P, \sigma, i, j_0, j_1, Q_0, Q_1)$  if and only if  $i \geq |\sigma|$ ,  $j_0 \neq j_1$ ,  $Q_0 \cap Q_1 = \emptyset$  and  $Q_k \subseteq P \wedge Q_k \Vdash \Phi_e^{H_n^x}(i) = j_k$  for  $k \leq 1$ . Obviously  $\mathcal{R}$  is a  $\Pi_1^1$  relation. By Kreisel's Uniformization Theorem, there is a partial  $\Pi_1^1$  function  $F : 2^\omega \times 2^{<\omega} \rightarrow (\omega)^3 \times (2^\omega)^2$  so that  $\mathcal{R}(P, \sigma, i, j_0, j_1, Q_0, Q_1)$  for some  $i, j_0, j_1, Q_0, Q_1$  if and only if  $\mathcal{R}(P, \sigma, F(P, \sigma))$ . Without loss of generality, we assume that if  $P \Vdash \Phi_e^{H_n^x}(i) = j_i$  then for all  $k \leq i$ ,  $P \Vdash \Phi_e^{H_n^x}(k) = j_k$  for some  $j_k$ . We do an induction on  $\omega$ . During the construction, we will define a  $\Pi_1^1$  sequence of conditions  $\{P_\sigma\}_{\sigma \in 2^{<\omega}}$ .

*Step 0.* Define  $P_\emptyset = S$ .

*Step  $n + 1$ .* For each  $\sigma \in 2^n$ , define  $P_{\sigma^\frown 0} = Q_0$ ,  $P_{\sigma^\frown 1} = Q_1$  if  $F(P_\sigma, \sigma) = (i, j_0, j_1, Q_0, Q_1)$ .

Define  $G(\sigma) = P_\sigma$ . Then  $G$  is a total  $\Pi_1^1$  and so  $\Delta_1^1$  function.

Note that for each  $\sigma$ ,  $G(\sigma^\frown 0) \cap G(\sigma^\frown 1) = \emptyset$  and if  $\sigma \preceq \tau$  then  $G(\sigma) \supseteq G(\tau)$ . Define

$$Q = \bigcap_n \bigcup_{\sigma \in 2^n} G(\sigma).$$

Then  $Q$  is a  $\Delta_1^1$  perfect set.

Define a function  $g : \bigcup_{i \in \omega} i \times 2^{i+1} \rightarrow \omega$  so that  $g(i, \sigma) = k$  if  $\sigma \in 2^{i+1}$  and  $G(\sigma) \Vdash \Phi_e^{H_n^x}(i) = k$ . Hence  $g$  is a total  $\Pi_1^1$  and therefore  $\Delta_1^1$  function. Define  $f(i) = j$  if  $j$  is the least number such that  $D_j = \{g(i, \sigma) \mid \sigma \in 2^{i+1}\}$ . Then  $f$  is a  $\Delta_1^1$  function and  $|D_{f(i)}| \leq 2^{i+1}$  for all  $i$ . Since for all  $i$ ,  $Q \subseteq \bigcup_{\sigma \in 2^n} G(\sigma)$ , it is easy to see that  $Q \Vdash \Phi_e^{H_n^x}(i) \in D_{f(i)}$ .

So  $x$  is  $\Delta_1^1$ -traceable. □

## 6. LOWNESS FOR $\Delta_1^1$ -RANDOMNESS

**Definition 6.1.** Given a relativizable class of reals  $\mathcal{C}$  (for instance,  $\mathcal{C}$  is the class of random reals), a real  $x$  is low for  $\mathcal{C}$  if  $\mathcal{C} = \mathcal{C}^x$ .

For a randomness notion  $\mathcal{C}$ , we have  $\mathcal{C}^x \subseteq \mathcal{C}$ , and usually one would expect  $\mathcal{C}^x$  to be a proper subset of  $\mathcal{C}$ . Thus being low for  $\mathcal{C}$  means to be computationally weak, in the sense that the extra computational power of  $x$  does not help to recognize more reals as nonrandom.

It is shown in [5] that  $x$  is low for  $\Pi_1^1$ -ML-randomness if and only if  $x$  is hyperarithmetical. The main result of this section is that a real is low for  $\Delta_1^1$ -randomness if and only if it is  $\Delta_1^1$ -traceable. This corresponds to the main result in [9] that a real  $A$  is low for Schnorr randomness if and only if it is recursively traceable. That result was an extension of the theorem in [22] that  $A$  is low for Schnorr tests if and only if it is recursively traceable. The equivalence of (i) and (ii) in the theorem below reveals this parallel phenomenon in the realm of effective descriptive set theory.

For  $D \subset 2^{<\omega}$  we let  $[D]^\preceq$  denote the open set  $\bigcup\{[\sigma] \mid \sigma \in D\}$ . We often identify an open set with the corresponding set of strings closed under extension. We let  $S_e$  be the  $e$ th finite subset of  $2^{<\omega}$  under a suitable effective enumeration. Thus  $S_e$  is a finite set of strings, and  $[S_e]^\preceq = \bigcup_{\sigma \in S_e} [\sigma]$  is then the clopen set coded by  $e \in \omega$ .

**Theorem 6.2.** The following are equivalent for a real  $x$ .

- (i)  $x$  is  $\Delta_1^1$ -traceable (or equivalently,  $\Pi_1^1$  traceable).
- (ii) Each  $\Delta_1^1(x)$  null set is contained in a  $\Delta_1^1$  null set.
- (iii)  $x$  is low for  $\Delta_1^1$ -randomness.
- (iv) Each  $\Pi_1^1$ -ML-random set is  $\Delta_1^1(x)$ -random.

*Proof.* (i)  $\rightarrow$  (ii): Assume that  $x$  is  $\Delta_1^1$ -traceable. Let  $\mathcal{S}$  be a  $\Delta_1^1(x)$  null set. By Lemma 3.2 relativized to  $x$ ,  $\mathcal{S} \subseteq \bigcap U_n$  for a  $\Delta_1^1(x)$ -ML test  $\{U_n\}_{n \in \omega}$  such that  $\mu(U_n) = 2^{-n}$  for each  $n$ . There is a function  $f \leq_h x$  such that  $[S_{f(\langle n, s \rangle)}]^\preceq =: U_{n,s}$  satisfies  $U_{n,s} \subseteq U_{n,s+1}$ ,  $U_n = \bigcup_{s \in \omega} U_{n,s}$ , and, moreover,  $\mu(U_{n,s}) > 2^{-n}(1 - 2^{-s})$ .

Let  $T = (T_e)_{e \in \omega}$  be a  $\Delta_1^1$  trace of  $f$ . By Proposition 5.2, we may choose  $T$  such that in addition  $|T_e| \leq e$  for each  $e > 0$ .

We now define a subtrace  $\hat{T}$  of  $T$ , i.e.,  $\hat{T}_{\langle n, s \rangle} \subseteq T_{\langle n, s \rangle}$  for each  $n, s$ . The objective is to define open sets  $V_n$  via  $\hat{T}$  (in a way to be specified) small enough to give us a  $\Delta_1^1$ -null set  $\mathcal{V} = \bigcap_n V_n$ , yet large enough as to keep all “relevant” reals out of  $T_{\langle n, s \rangle} - \hat{T}_{\langle n, s \rangle}$ , so that  $\bigcap_{n \in \omega} U_n \subseteq \mathcal{V}$ .

Let  $\hat{T}_{\langle n, s \rangle}$  be the set of  $e \in T_{\langle n, s \rangle}$  such that  $2^{-n}(1 - 2^{-s}) \leq \mu([S_e]^\preceq) \leq 2^{-n}$  and  $[S_e]^\preceq \supseteq [S_d]^\preceq$  for some  $d \in \hat{T}_{\langle n, s-1 \rangle}$  (where  $\hat{T}_{\langle n, -1 \rangle} = \omega$ ). Note that  $f(\langle n, s \rangle) \in \hat{T}_{\langle n, s \rangle}$ . Let

$$V_n = \bigcup \left\{ [S_e]^\preceq \mid e \in \hat{T}_{\langle n, s \rangle}, s \in \omega \right\}.$$

Then  $\mu(V_n) \leq 2^{-n}|\hat{T}_{\langle n, 0 \rangle}| + \sum_{s \in \omega} 2^{-s}2^{-n}|\hat{T}_{\langle n, s \rangle}|$ . Since  $|\hat{T}_{\langle n, s \rangle}| \leq |T_{\langle n, s \rangle}| \leq \langle n, s \rangle$  for  $\langle n, s \rangle \neq 0$ , and  $\langle n, s \rangle$  has only polynomial growth in  $n$  and  $s$ , it is clear that  $\lim_n \sum_{s \in \omega} 2^{-s}2^{-n}|\hat{T}_{\langle n, s \rangle}| = 0$ , and hence  $\lim_n \mu(V_n) = 0$ . Then  $\mathcal{V} = \bigcap_n V_n$  is a  $\Delta_1^1$ -null set and  $\bigcap U_n \subseteq \mathcal{V}$ .

(ii)  $\Rightarrow$  (iii) and (iii)  $\Rightarrow$  (iv) are immediate.

(iv)  $\Rightarrow$  (i): In [9, Lemma 4.7], it is shown that, if each ML-random set is Schnorr random relative to  $x$ , then  $x$  is r.e. traceable. With merely notational changes, the proof works in the present situation. First some preliminaries. Recall that  $K(\sigma)$  denotes the  $\Pi_1^1$  version of prefix free Kolmogorov complexity. For  $b \in \omega - \{0\}$ , let  $R_b = [\{\sigma \in 2^{<\omega} \mid K(\sigma) \leq |\sigma| - b\}]$ . In [5, Theorem 3.9] it is shown that  $(R_b)_{b \in \omega}$  is a universal test for  $\Pi_1^1$ -ML-randomness. Thus, by our hypothesis in (iv), we have  $\mathcal{C} \subseteq \bigcap_b R_b$  for each  $\Delta_1^1(x)$  null set  $\mathcal{C}$ .

For  $k, l \in \omega$  define the clopen set

$$B_{k,l} = \bigcup \{[\tau 1^k] \mid \tau \in 2^{<\omega}, |\tau| = l\},$$

where  $1^k$  is a string of 1's of length  $k$ . Note that  $\mu(B_{k,l}) = 2^{-k}$  for all  $l$ .

Given  $\sigma \in 2^{<\omega}$  and a measurable set  $C \subseteq 2^\omega$ , let  $\mu_\sigma(C) = \frac{\mu(C \cap [\sigma])}{\mu[\sigma]}$ . For an open set  $W$  let

$$W|\sigma = \bigcup \{[\tau] \mid \tau \in 2^{<\omega}, [\sigma\tau] \subseteq W\}.$$

Now to find a trace for a given function  $g \leq_h x$ , define the  $\Delta_1^1(x)$ -ML test  $U^g$  by stipulating that

$$U_n^g = \bigcup_{k > n} B_{k,g(k)}.$$

Hence by assumption  $\bigcap_n U_n^g \subseteq \bigcap_{b \in \omega} R_b$ . Thus  $V = R_3$  contains  $\bigcap_n U_n^g$  and  $\mu(V) < \frac{1}{4}$ . We may assume throughout that  $g(k) \geq k$  for every  $k$  because from a trace for  $g(k)+k$  one can obtain a trace for  $g$  with the same bound. By [9, Lemma 4.4], there exist  $\sigma$  and  $n$  such that  $\mu_\sigma(U_n^g - V) = 0$  and  $\mu_\sigma(V) < 1/4$ . As  $U_0^g \supseteq U_1^g \supseteq \dots$ , we can

choose  $\sigma$  and  $n$  with the additional property  $n \geq |\sigma|$ . Hence for each  $k > n$ , we have  $g(k) \geq k > n \geq |\sigma|$  and hence  $g(k) \geq |\sigma|$ .

Let  $\tilde{V} = V|\sigma$ , let  $\tilde{g}(k) = \max\{0, g(k) - |\sigma|\}$ , and

$$T_k = \left\{ l \mid \mu(B_{k,l} - \tilde{V}) < 2^{-(l+3)} \right\}.$$

Note that for each  $l \in \omega$ , if  $l \geq |\sigma|$  then  $B_{k,l}|\sigma = B_{k,l-|\sigma|}$ . So since  $g(k) \geq |\sigma|$ ,

$$U_n^g|\sigma = \bigcup_{k>n} B_{k,g(k)}|\sigma = \bigcup_{k>n} B_{k,g(k)-|\sigma|} = U_n^{\tilde{g}},$$

and we obtain  $\mu(U_n^{\tilde{g}} - \tilde{V}) = \mu_\sigma(U_n^g - V) = 0$ . Hence  $\tilde{g}(k) \in T_k$  for all  $k > n$ .

Since  $\tilde{V}$  is a  $\Pi_1^1$  open set, it is evident that  $T$  is a  $\Pi_1^1$  set of integers. A trace for  $g$  is obtained as follows:

$$G_k = \begin{cases} \{l + |\sigma| \mid l \in T_k\} & \text{if } k > n; \\ \{g(k)\} & \text{if } k \leq n. \end{cases}$$

We now show that  $G$  is a trace for  $g$ , i.e. for all  $k \in \omega$ ,  $g(k) \in G_k$ . If  $k \leq n$  then this holds by definition of  $G_k$ . Thus assume  $k > n$ . Then  $g(k) > k > n > |\sigma|$ , so  $\tilde{g}(k) = g(k) - |\sigma|$  so  $g(k) = \tilde{g}(k) + |\sigma|$ . As  $k > n$ ,  $\tilde{g}(k) \in T_k$  and hence  $g(k) \in G_k$ .

Clearly  $G$  is  $\Pi_1^1$ ; so it remains to show that  $|G_k|$  is hyperarithmetically bounded, independently of  $g$ . As  $|G_k| = |T_k|$  for  $k > n$  and  $|G_k| = 1$  for  $k \leq n$ , this is a consequence of Lemma 4.8 of [9], reproduced below.  $\square$

**Lemma 6.3** ([9]). *If  $\tilde{V}$  is a measurable set with  $\mu(\tilde{V}) < \frac{1}{4}$ , and  $T_k = \{l \mid \mu(B_{k,l} - \tilde{V}) < 2^{-(l+3)}\}$ , then for  $k \geq 1$ ,  $|T_k| < 2^k k$ .*

**Corollary 6.4.** *There exists a  $\Delta_1^1$ -dominated real which is not  $\Delta_1^1$ -traceable.*

*Proof.* By Theorem 4.2,  $\Delta_1^1$ -dominated reals form a measure 1 set but, by Theorem 6.2, the set of  $\Delta_1^1$ -traceable reals form a null set, being disjoint from the set of  $\Delta_1^1$ -random reals.  $\square$

## 7. CONCLUDING REMARKS

A real  $x$  is said to be  $\Pi_1^1$ -random cuppable, or random cuppable for short, if  $x \oplus y \geq_h \mathcal{O}$  for all  $\Pi_1^1$ -random reals  $y$ . It is known [5] that if  $x$  is low for  $\Pi_1^1$ -randomness then  $\omega_1^{\text{CK}} = \omega_1^x$ . Harrington, Nies and Slaman have obtained a further result on lowness for  $\Pi_1^1$ -randomness. We include a proof of this result here.

**Theorem 7.1** (with Harrington and Slaman). *A real  $x$  is low for  $\Pi_1^1$ -randomness if and only if  $x$  is low for  $\Delta_1^1$ -randomness and not random cuppable.*

*Proof.* For the direction from left to right, suppose  $x$  is low for  $\Pi_1^1$ -randomness, that is, each  $\Pi_1^1$ -random real is  $\Pi_1^1(x)$ -random. Since  $x \not\geq_h \mathcal{O}$ , the  $\Pi_1^1(x)$  set  $\{y \mid y \oplus x \geq_h \mathcal{O}\}$  is null, by relativizing Theorems 2.3 and 2.4. Thus  $x$  is not random cuppable. To see that  $x$  is low for  $\Delta_1^1$ -randomness, suppose for a contradiction that  $y$  is a  $\Delta_1^1$ -random real that is not  $\Delta_1^1(x)$ -random. Thus there is a  $\Delta_1^1(x)$ -null set  $A$  containing  $y$ . By the

main result in Martin-Löf [11], the null set  $B = \bigcup\{C \subset 2^\omega \mid \mu(C) = 0 \wedge C \text{ is } \Delta_1^1\}$  is  $\Pi_1^1$ . Since  $y \in A - B$ ,  $A - B$  is a nonempty  $\Sigma_1^1(x)$  set. By the Gandy Basis Theorem 2.1 relative to  $x$ , there is a real  $z \in A - B$  so that  $\omega_1^{z \oplus x} = \omega_1^x = \omega_1^{\text{CK}}$ . Then  $z$  is  $\Delta_1^1$ -random but not  $\Delta_1^1(x)$ -random, so by Corollary 3.5 and its relativization to  $x$ ,  $z$  is  $\Pi_1^1$ -random but not  $\Pi_1^1(x)$ -random, a contradiction.

For the other direction, suppose  $x$  is low for  $\Delta_1^1$ -randomness and not random cuppable. Then  $x \not\geq_h \mathcal{O}$ . Suppose  $z$  is a  $\Pi_1^1$ -random real. By the proof of Theorem 3.4 relative to  $x$ , the largest  $\Pi_1^1(x)$  null set  $\mathcal{Q}(x)$  is a union of countably many  $\Delta_1^1(x)$  null sets  $\mathcal{Q}_n(x)$  and the  $\Pi_1^1(x)$  null set  $\{y \mid y \oplus x \geq_h \mathcal{O}\}$ . Since  $x$  is low for  $\Delta_1^1$ -randomness,  $z \notin \bigcup_n \mathcal{Q}_n(x)$ . Since  $x$  is non- $\Pi_1^1$ -random cuppable,  $z \oplus x \not\geq_h \mathcal{O}$ . So  $z$  is  $\Pi_1^1(x)$ -random.  $\square$

The following question remains open:

**Question 7.2.** *Is there a real  $x$  that is low for  $\Pi_1^1$ -randomness but not hyperarithmetical?*

Reimann and Slaman have shown that if  $x$  is not 1-random relative to any continuous measure, then  $x$  is hyperarithmetical. In an analogy, one can ask:

**Question 7.3.** *Is there a characterization of the reals  $x$  that are not  $\Pi_1^1$ -ML-random, or the ones that are not  $\Delta_1^1$ -random relative to any continuous measure?*

One may also study higher genericity theory as has been done for classical genericity theory ([23] and [20]). The third author has proved that lowness for  $\Pi_1^1$ -genericity is the same as being hyperarithmetical and there exists a non-hyperarithmetical real that is low for  $\Delta_1^1$ -genericity.

The results of the previous sections show that several of the key notions of randomness, demonstrably different in first order theory, coalesce into equivalent ones in effective descriptive set theory. Thus finer distinctions are revealed only at the arithmetic level. It is tempting to venture beyond  $\Pi_1^1$  and  $\Delta_1^1$  and explore the landscape of definable randomness in the analytical hierarchy. However, this will lead us very quickly to statements undecidable in  $ZFC$ . Assuming *projective determinacy* ( $PD$ ), Kechris [6] has proved several measure and category-theoretic results in the analytical hierarchy in parallel with results for the  $\Pi_1^1$  case in [17].<sup>1</sup> We believe that most of the results proved in the previous sections remain valid upon replacing  $\Pi_1^1$  with  $\Pi_{2n+1}^1$  or  $\Sigma_{2n}^1$  under  $PD$ . However it seems that  $PD$  is not a correct tool to use for analyzing the analytical sets since it provides limited recursion-theoretic information. For example,  $PD$  does not give a ramified analytical hierarchy with properties similar to what one has for  $\Pi_1^1$  sets. Instead, some deep results in inner model theory are necessary for this. Inner model theory (say  $Q$ -theory [8]) has been applied by some to study descriptive set theory in order to obtain powerful characterizations

---

<sup>1</sup>Since one may apply  $PD$  to obtain some dynamic properties of  $\Pi_{2n+1}^1$  and  $\Sigma_{2n}^1$ -sets, such as scales (see [12]).

of analytical sets (under large cardinal assumptions, see [8])<sup>2</sup>. The results are of recursion-theoretic interest, and this area is worth further investigation.
